Prelims_HCAI.indd 10 17-09-2020 09:53:39

FOREWORD

Healthcare-associated infections (HCAIs) are a global phenomenon, the fact underscored by the current pandemic of SARS-CoV-2 infection. Patients admitted in a healthcare facility/healthcare professionals providing medical care/services and visitors to the hospital, all are at risk of acquiring an infection during their stay in the facility/hospital. The degree of risk varies from facility to facility, country to country, host factors, type of hospital, type of patient population, type of infection prevention and control practices, antimicrobial management, and many other factors. An ever-increasing range of these infections is being caused by the resistant superbugs, namely multidrug resistant (MDR), extensively drug resistant (XDR), pandrug resistant (PDR) (including bacteria, parasites, viruses, and fungi) and newly emerging microorganisms including viruses like MERS and SARS-CoV-2. The misuse of antimicrobials leads to development of resistant microorganisms and transmission of these viruses through laxity in infection control practices like hand hygiene, contact precautions, and airborne precautions. HCAIs caused by such highly resistant newly emerged microorganisms (SARS-CoV-2) are a serious threat to patient's safety and global public health. Such infections result in worse clinical outcomes like death and high cost. New resistant microorganisms and new viruses continuously emerge and spread in the hospital and the community. The appropriate use of antimicrobial agents to prevent emergence of resistant superbugs and a robust infection prevention and control program are the two most important strategies to prevent/contain emergence and transmission of resistant microorganisms and newly emerging viruses like SARS-CoV-2 that cause HCAIs, locally and globally.

A lot of literature and guidelines on infection prevention and control are available in print and on websites. However, most of these pertain to and refer to facilities available in other/developed nations. Medical professionals in developing countries like ours are many a times at loss to decide as to what best can be done in a particular situation/facility within the limited available resources and facilities to control HCAIs.

This book deals with all the relevant details of various HCAIs (including COVID-19) giving risk factors, how and why HCAIs happen, how to treat these, how to break the various links in the chain of infection in the hospital, how to develop, implement, and monitor various infection prevention and control policies, procedures and protocols taking into account the latest published literature and guidelines, and adapting them to our situation.

I am sure this book will be of immense help to experts functioning at different levels of healthcare (primary, mid-level, and tertiary care centers in public and private sectors) in the development and implementation of need-based infection prevention and control program for already existing and newly emerging infections like COVID-19, successfully.

I congratulate Dr Usha Krishan Baveja, a renowned medical microbiologist, Dr Yatin Mehta, a renowned critical care specialist, both also being experienced infection preventionists, and all the expert contributors for their commendable efforts for the book. We hope our doctors will use the book and help to prevent and control the existing and newly emerging (COVID-19) HCAIs in healthcare facilities/hospitals.

Naresh Trehan MD (Diplomate American Board of surgery/Cardiac surgery) FRCP MRCP
Chairman and Managing Director
Medanta – The Medicity
Gurugram, Haryana, India
Awarded: Padma Bhushan and Padma Shri

PREFACE

Healthcare-associated infections (HCAIs), the most important preventable inpatient global problem that are adversely affecting the patient safety as well as the safety of care providers. The fact has been amply emphasized by the ongoing pandemic of SARS-CoV-2 infection. The burden of HCAIs is not exactly known in our country. However, there are reports suggesting that HCAIs are an increasing problem associated with adverse patient outcomes including death. Why this is so? Why the HCAIs have become a serious national and global problem?

One important factor for HCAIs is the rapid advances in medical technology and improved delivery of healthcare with the increasing use of devices, implants, and prostheses, particularly in an aging population. Inappropriate use of these inert devices/implants leads to colonization by microorganisms, formation of a biofilm, and finally an infection.

Another factor is the increased life expectancy today, resulting in a large population of vulnerable patients seeking care in hospitals including patients at extremes of age groups, inpatients with devices and implants, patients on immunosuppressive therapy, oncology patients, post-transplant cases, and so on. Such cases stay in the hospital for long period of time, receive multiple antibiotics, and are exposed to hospital superbugs through various means. The device-related HCAIs like central line-associated infections, catheter-associated urinary tract infections, and ventilator-associated events including pneumonia are common in patients with long stay in hospital particularly in critical care. Majority of HCAIs are associated with implantable devices such as catheters.

Inappropriate use of antimicrobial agents in the community as well as in hospitals resulting in the emergence and transmission of superbugs [such as methicillin-resistant Staphylococcus aureus (MRSA), vancomycin-resistant *Staphylococcus* aureus (VRSA), vancomycin-resistant *Enterococcus* (VRE), carbapenem-resistant *Enterobacteriaceae* (CRE), *Pseudomonas aeruginosa* and *Acinetobacter* species, extended-spectrum beta-lactamase (ESBL)-producing *Enterobacteriaceae*, and newer non-*Candida* fungi including *Candida auris*] causing HCAIs is an additional threat to patient safety. Antimicrobial resistance contributes to the treatment failure, complications, and mortality in patients having HCAIs caused by such resistant microorganisms. Emerging zoonotic viral infections like H1N1, MERS and COVID-19 (SARS-CoV-2), for some of which successful treatment prophylaxis and vaccination are not yet available are transmitted in the hospital setting from infected patients to other patients and healthcare personnel, thus adding to the problem.

The availability of a large number of antimicrobial agents led to a false sense of security among clinicians resulting in carelessness in practice of simple infection control measures like hand hygiene and consequent transmission of microorganisms and infections. HCAIs have emerged as a serious threat to inpatient care. This threat can only be challenged through diligent infection prevention and infection control practices and the rational use of antimicrobial agents, antimicrobial stewardship by every healthcare provider in every department of the hospital aimed at prevention of transmission of superbugs and newly emerged viruses like SARS-CoV-2. The present book is a step in this direction.

This book details the basic science of infection, the microorganisms circulating in a hospital, and the antimicrobial agents available including the rational use of these along with antimicrobial stewardship. There are chapters describing A, B, C of various HCAIs including COVID-19 caused by SARS-CoV-2 and how to develop a need-based infection prevention and control program (IPCP) for different levels of healthcare to prevent HCAIs. There are many chapters describing strategies of IPCP including hand hygiene, standard precautions, airborne and contact precautions, sterilization and disinfection, central sterilization and supplies, laundry management, biomedical waste management, and so on. Infection prevention and control in various areas of the hospital for various groups of patients, role of nursing, and role of microbiology laboratory to prevent and control HCAIs are described. There are chapters on investigation of an outbreak, maintenance of occupational health of healthcare professionals (HCPs), maintenance of clean environment, heating, ventilation, and air conditioning (HVAC) system, OTs, ICUs and negative pressure rooms, etc. The latest strategies to prevent infections in different possible situations (ICU, HDU, post transplant units and Burns unit, etc.) in a healthcare facility including the clinical laboratory are described.

Prelims_HCAI.indd 13 17-09-2020 09:53:39

Each chapter has been contributed by experts who are knowledgeable, conversant with the latest knowledge on the subject, and are involved in implementing the program in their respective hospitals. The chapters are structured in a way (with MCQs at the end) that the book can be used for training and education. In addition, there are chapters providing teaching and training materials for prevention of HCAIs including COVID-19 and laboratory-acquired infections (LAIs), respectively.

We have tried to include the details of all aspects of prevention of HCAIs—infection prevention and control in such a way that the reader will be able to understand, develop, and implement the IPCP in his/her hospital and train the HCPs to help contain this menace of HCAIs. We hope the tome will be useful for each and every individual engaged in providing healthcare services to practice infection prevention and control and thus reduce HCAIs in hospitals, hospices and other healthcare institutions.

Usha Krishan Baveja
Yatin Mehta

ACKNOWLEDGMENTS

We thank the God Almighty for blessing us with knowledge, energy, clarity, and continuous support received in bringing forth this book.

We thank our parents and teachers for educating, guiding, and enabling us to think and understand the subject and help to prepare the book to prevent infections and thus improve patient care.

We thank our family members and our friends for their support and helpful suggestions.

We thank each and every author for his/her contribution, for the precise knowledge presented lucidly in the chapters contributed, to enable the readers to understand and implement the practices as relevant to their respective healthcare facilities.

We thank Ms Poonam Anand for rendering secretarial support as and when required.

We are most grateful to Jaypee Brothers Medical Publishers (P) Ltd, the publishers who understood the importance of the subject of healthcare-associated infections and encouraged us to edit this book on prevention and control of these infections. Last but not the least, we express our thanks to the Editorial team at Jaypee Brothers Medical Publishers (P) Ltd for their constant support and suggestions to improve the book.

We hope that the readers will find this book easy to understand and useful, and this will help them to put the knowledge gained into effective infection control practices to prevent and control healthcare-associated infections.

Usha Krishan Baveja

FOREWORD

Pediatric Endocrinology is one of the important emerging specialities of Pediatrics. Endocrine glands affect directly or indirectly all organs of body and may cause organ dysfunction. An early diagnosis of problem is of paramount importance as it helps in early institution of treatment and prevents damage to organs. Pediatricians need to know about various disorders, diagnostic algorithm and treatment of disorders arising out of malfunctioning of endocrine glands. There are books on Pediatric Endocrinology but these are written for specialist training. There is a lack of book that can be a table reference for a Pediatrician.

This multi-author book entitled "Practical Pediatric Endocrinology" is written; keeping Pediatricians as target audience. The authors are well known experts with long experience in managing children with endocrine disorders. They have provided simple algorithmic approach about suspecting, diagnosis, management and monitoring of children and adolescents with various endocrine disorders.

Indian Journal of Pediatrics publishes books to improve child health and survival. We are confident that this book will be of immense value to Pediatric residents, practicing Pediatricians and clinicians with special interest in Endocrinology. It will also serve as an initial reference book for all specialist pediatricians to suspect, diagnose and institute initial management awaiting consultation with Pediatric Endocrinologist.

Chapter 6

Thyrotoxicosis

Rahul Jahagirdar and Nikhil Lohiya

Background

Hyperthyroidism is a condition that occurs due to excessiv oduction of thyroid hormones by the thyroid gland. Thyrotoxicosis is a dition that occurs due to excessive thyroid hormone due to any cause therefore includes hyperthyroidism. These terms are often used inte angeably.

Hyperthyroidism is a state of thyroid characterized by excess of thyroid hormones including thyroxine (T4) and tri-iodothyronine (T3). It is a less common endocrine problem in children but has significant therapeutic considerations. The most common etiology of hyperthyroidism in children is Graves disease caused due to thyroid stimulating hormone (TSH) receptor activating antibodies.

Pathophysiology

Thyrotoxicosis is caused by either increased production or release of thyroid hormones.

- In Graves hyperthyroidism there are TSH receptor antibodies (TSH-R-Ab) which activate the TSH receptors and cause excessive synthesis and secretion of thyroid hormones (T3 & T4).
- The same antibodies act against the TSH receptor-like protein in retroorbital connective tissue leading to Graves ophthalmopathy.
- There is a family history of autoimmune disorder in patients with Graves disease.
- Release of preformed hormones occurs in thyroiditis, which can be bacterial, viral or immune in origin. They usually do not have the eye signs as seen in Graves disease.
- Hyperthyroidism can be seen in McCune-Albright syndrome which occurs due to activating mutation of α-subunit of the G-protein; they tend to have a multi-nodular goiter.

Etiology

Etiology of hyperthyroidism is shown in Fig. 1.

Clinical Evaluation

The onset of clinical manifestations in children with hyperthyroidism is insidious; changes may be present for months or even years before the diagnosis is made.

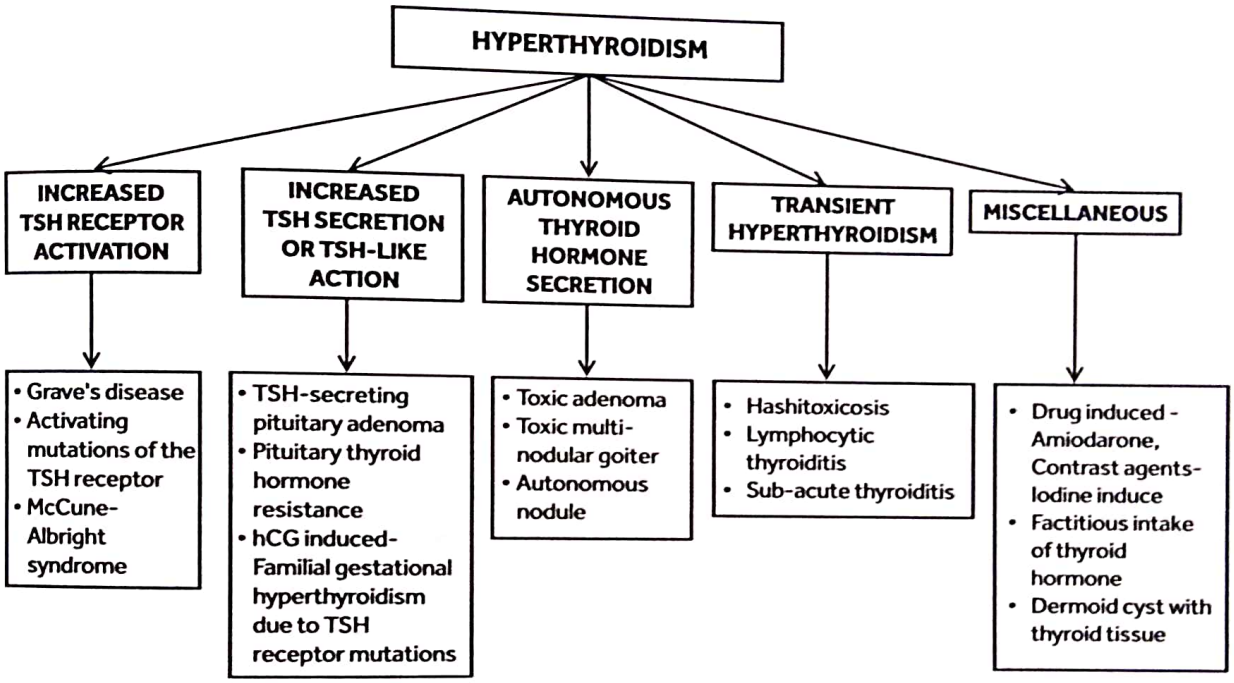

Fig. 1. Etiology of hyperthyroidism.

hCG Human chorionic gonadotropin; *TSH* Thyorid stimulating hormone

- ***Goiter:*** Enlargement of thyroid gland is seen in children with hyperthyroidism. The clinical findings vary with the etiology. In Graves disease, the goiter is diffuse with a smooth surface, fleshy in consistency with no nodules. In Hashitoxicosis, the goiter will be diffusely enlarged with bosselated surface and firm consistency. In subacute thyroiditis, goiter is generally painful. In multinodular goiter, there is enlarged thyroid with multiple nodules. A single nodule in thyroid gland without goiter is seen in autonomous thyroid nodule. On auscultation, a bruit can often be noted over the gland in hyperthyroid patients.
- ***Eyes:*** Exophthalmos is one of the cardinal features of Graves disease. Though observed in children, it is milder than adults. There is lid lag and stare look. Proptosis with impaired movement of eye and periorbital edema has been observed. There could be pain in the eyes with gritty feel (Fig. 2).

Fig. 2. Clinical picture of a 12-y-old girl child with hyperthyroidism. Classical exophthalmos can be made out.

[Child's assent and parents consent was obtained for publishing the photograph]

- ***Growth*:** Children with hyperthyroidism of long standing like Graves disease can have accelerated growth with advanced bone age. The duration of 1-2 y of illness might increase the height from 50th centile to 75th centile. The final height achieved by these children is in their target range due to relatively advanced bone age.
- ***Puberty:*** The age of attainment of puberty is not affected by hyperthyroidism. However, girls who have undergone menarche can complaint of oligomenorrhea or secondary amenorrhea.
- ***Cardiovascular:*** There could be tachycardia with high blood pressure. The blood pressure will show wide pulse pressure due to decrease in peripheral vascular resistance.
- ***Gastrointestinal:*** There could be a loss of weight despite good appetite. The gut motility is increased leading to increased frequency of stool passage. The children might not be necessarily underweight at the time of diagnosis.
- ***Neuro-psychologic:*** Tremors or tremulousness can be seen in hyperthyroidism. Ataxia, chorea and exaggerated deep tendon reflexes may be present. Occasionally there might be personality changes,

agitation, depression, mania, or psychosis. The attention span is reduced, poor sleep, deterioration in school performance and hyperactivity might be observed in children with hyperthyroidism.

- ***Bone & muscle:*** Proximal muscle weakness with decreased muscle mass and decreased efficiency of muscle contraction is also observed in hyperthyroidism. Hypokalemic periodic paralysis is also observed in children, especially of Asian descent. Thyroid hormone causes resorption of bone, hence resulting in increased porosity of cortical bone and reduction in volume of trabecular bone.
- ***Lipid metabolism:*** There is a low serum total cholesterol and high density lipoprotein (HDL) levels.
- ***Skin:*** Increased perspiration is seen in the skin. Onycholysis and increased hair loss might also be present. Presence of café-au-lait spots suggests McCune Albright syndrome.

Diagnostic Evaluation

The diagnosis of thyrotoxicosis is confirmed by constellation of classical clinical features and increased thyroid hormone levels. The diagnostic work-up can be divided in following headings -

a) Biochemistry- Thyroid function test

b) Serology- Antibodies assessment

c) Imaging- Ultrasound and radio-iodine uptake scan

a. *Biochemistry– Thyroid function test*

- TSH is the most sensitive and specific single blood test indicated in evaluation of hyperthyroidism.The diagnostic accuracy improves when free T4 is done along with TSH. TSH and free T4 share an inverse log linear relationship.
- When hyperthyroidism is overt, both free T4 and free T3 will be elevated. Low TSH with normal free T4 levels suggests subclinical thyrotoxicosis, which is uncommon in children.
- T3 toxicosis should be considered in the settings of normal free T4 and low TSH levels and clinical features of thyrotoxicosis. Assessment of T3 levels would be helpful in this situation.

b. *Serology- Antibodies assessment*

- After establishing that the patient is hyperthyroid, the next step is to work-up for the etiology.
- TSH receptor antibody (TSH-R-Ab) is typically po ive in Graves disease.
- Other autoimmune antibodies including anti O (thyroid peroxidase) antibodies and anti TG (thyroglobulin) bodies can be positive or negative.
- In case of Hashitoxicosis, the TSH-R-Ab will be nega and other antibodies (anti-TPO and anti-TG) will be positive.

c. *Imaging*

- Thyroid ultrasound is a convenient, non-invasive, rapid, and accurate tool.
- Vascular pattern can also be observed and helpful with the Doppler examination quantifying the thyroid vascularity.
- Graves disease is characterized by diffuse thyroid enlargement and hypo-echogenicity with increased vascularity with a typical pulsatile pattern.
- Multinodular goiter will show diffuse enlargement and hypoechogenicity.
- Solitary nodule, if it is a source of thyroid hormone, might also be seen in thyroid gland.
- Thyroid scan can also be performed with radio-iodine which will show high I-123 uptake in Graves disease and mildly elevated or normal uptake in Hashitoxicosis.
- Blunted I-123 uptake can be seen in iodine induced hyperthyroidism, factitious intake of thyroxine and also in sub-acute thyroiditis.

Algorithmic approach to etiological diagnosis of hyperthyroidism is shown in Fig. 3.

Management

a. *Medical treatment*

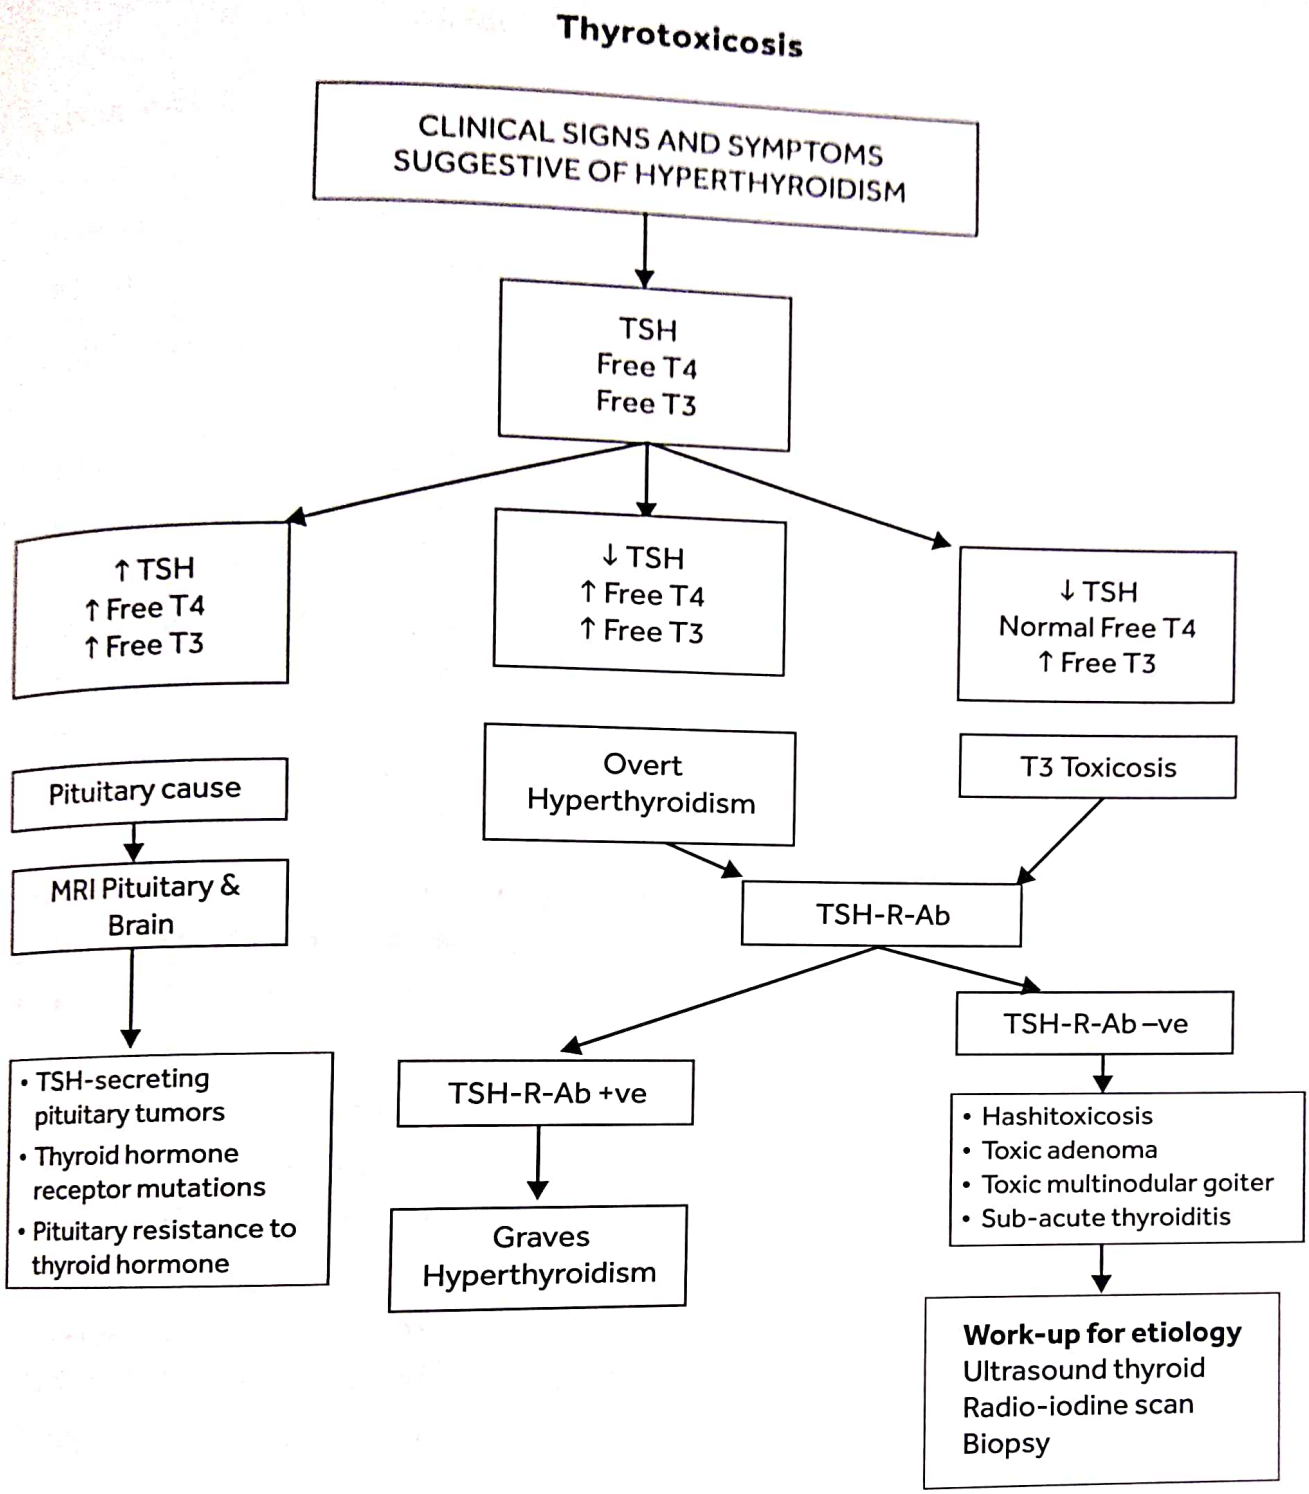

Fig. 3. Algorithmic approach to etiological diagnosis of hyperthyroidism. *MRI* Magnetic resonance imaging; *TSH* Thyroid stimulating hormone; *TSH-R-Ab* TSH receptor antibodies

- *Anti-thyroid drugs (ATDs)*
  - ❖ These drugs inhibit the synthesis of thyroid hormone.
  - ❖ The main drugs are thionamides including Propylthiouracil (PTU), Carbimazole (CBZ) and Methimazole (MMI).
  - ❖ Carbimazole is not the active metabolite but has to be

decarboxylated to Methimazole in liver which is the active metabolite.

- ❖ Thionamides inhibits coupling of iodothyronines, enzyme thioperoxides, reduce oxidation and organification of iodide.
- ❖ ATDs are the first line of treatment in pediatrics especially in children <5 y and between 5-10 y of age.
- ❖ PTU has a short half-life (90 min) requiring frequent administration and is also hepatotoxic especially in children. Hence, MMI (0.5 to 1 mg/kg/d) is preferred in children.
- ❖ Adverse effects of MMI include rash, arthralgia and urticaria which are most common. Patients should be warned about the adverse effect of agranulocytosis; which though rare, whenever child develops fever and sore throat a complete blood count is warranted and MMI should be withheld.
- ❖ The two methods of treatment are block and replacement regimen where ATD is given to completely suppress the thyroid biosynthesis inducing hypothyroidism and thyroid hormone is supplemented.
- ❖ In tapering dose method, MMI is initiated in such a way that thyroid biosynthesis is not completely suppressed. The dose of MMI is adjusted to keep free T4 and free T3 in the normal range and thyroxine is not added.
- ❖ The antithyroid drugs are continued for about two years, as maximum remission is expected in this duration

- *Beta-adrenergic blockade*
  - ❖ Propranolol is useful in controlling the adrenergic symptoms including palpitations and tremors.
  - ❖ It also helps in converting T4 to T3.
  - ❖ It is usually started along with MMI for initial symptomatic relief and once remission is achieved, it can be tapered and stopped.
- *Radio-iodine*
  - ❖ Radioactive iodine (RAI), also called as I-131, can be used to treat hyperthyroidism. RAI mainly gets accumulated in the thyroid gland and emits radiation which destroys the gland.

- ❖ In order to achieve thyroid ablation, the dose above 150 uCi of I-131 per gram of thyroid tissue needs to be administered. Lower dose administration of RAI predisposes to risk of thyroid malignancy.
- ❖ Thyroid storm is a potential adverse effect which can occur immediately post-treatment. Hence pre-treatment with MMI is recommended to prevent it.
- ❖ Long-term genetic damage is not known to be due to I-131 treatment.
- ❖ RAI is contraindicated in children younger than 5 y, as it poses to higher risk of thyroid malignancy in future.

b. Surgery

- When definitive therapy is required in children <5 y of age, surgery is the treatment of choice.
- In individuals with large thyroid gland (>80 g) the response to RAI may be poor and hence surgery is preferred as the 2nd line or definite therapy.
- Near total or total thyroidectomy is recommended and not sub-total thyroidectomy as it is associated with high relapse rate.
- The surgery is best done by an experienced high-volume surgeon in a well-equipped clinical setup.
- Post-surgery, lifelong thyroxine replacement is required.

Approach to management of hyperthyroidism is shown in Fig. 4.

Table 1 shows the choice of therapy in Graves disease.

Table 1. Choice of therapy in Graves disease

Therapy	< 5 y	5-10 y	>10 y
First-line therapy	Anti-thyroid drugs (Methimazole)	Anti-thyroid drugs (Methimazole)	Anti-thyroid drugs/ Radio-iodine
Second-line therapy	Surgery	Large goiter (>80 g)- Surgery Radio-iodine - If cumulative dose required is low.	Anti-thyroid drugs/ Radio-iodine
Third-line therapy	--	Surgery	Surgery

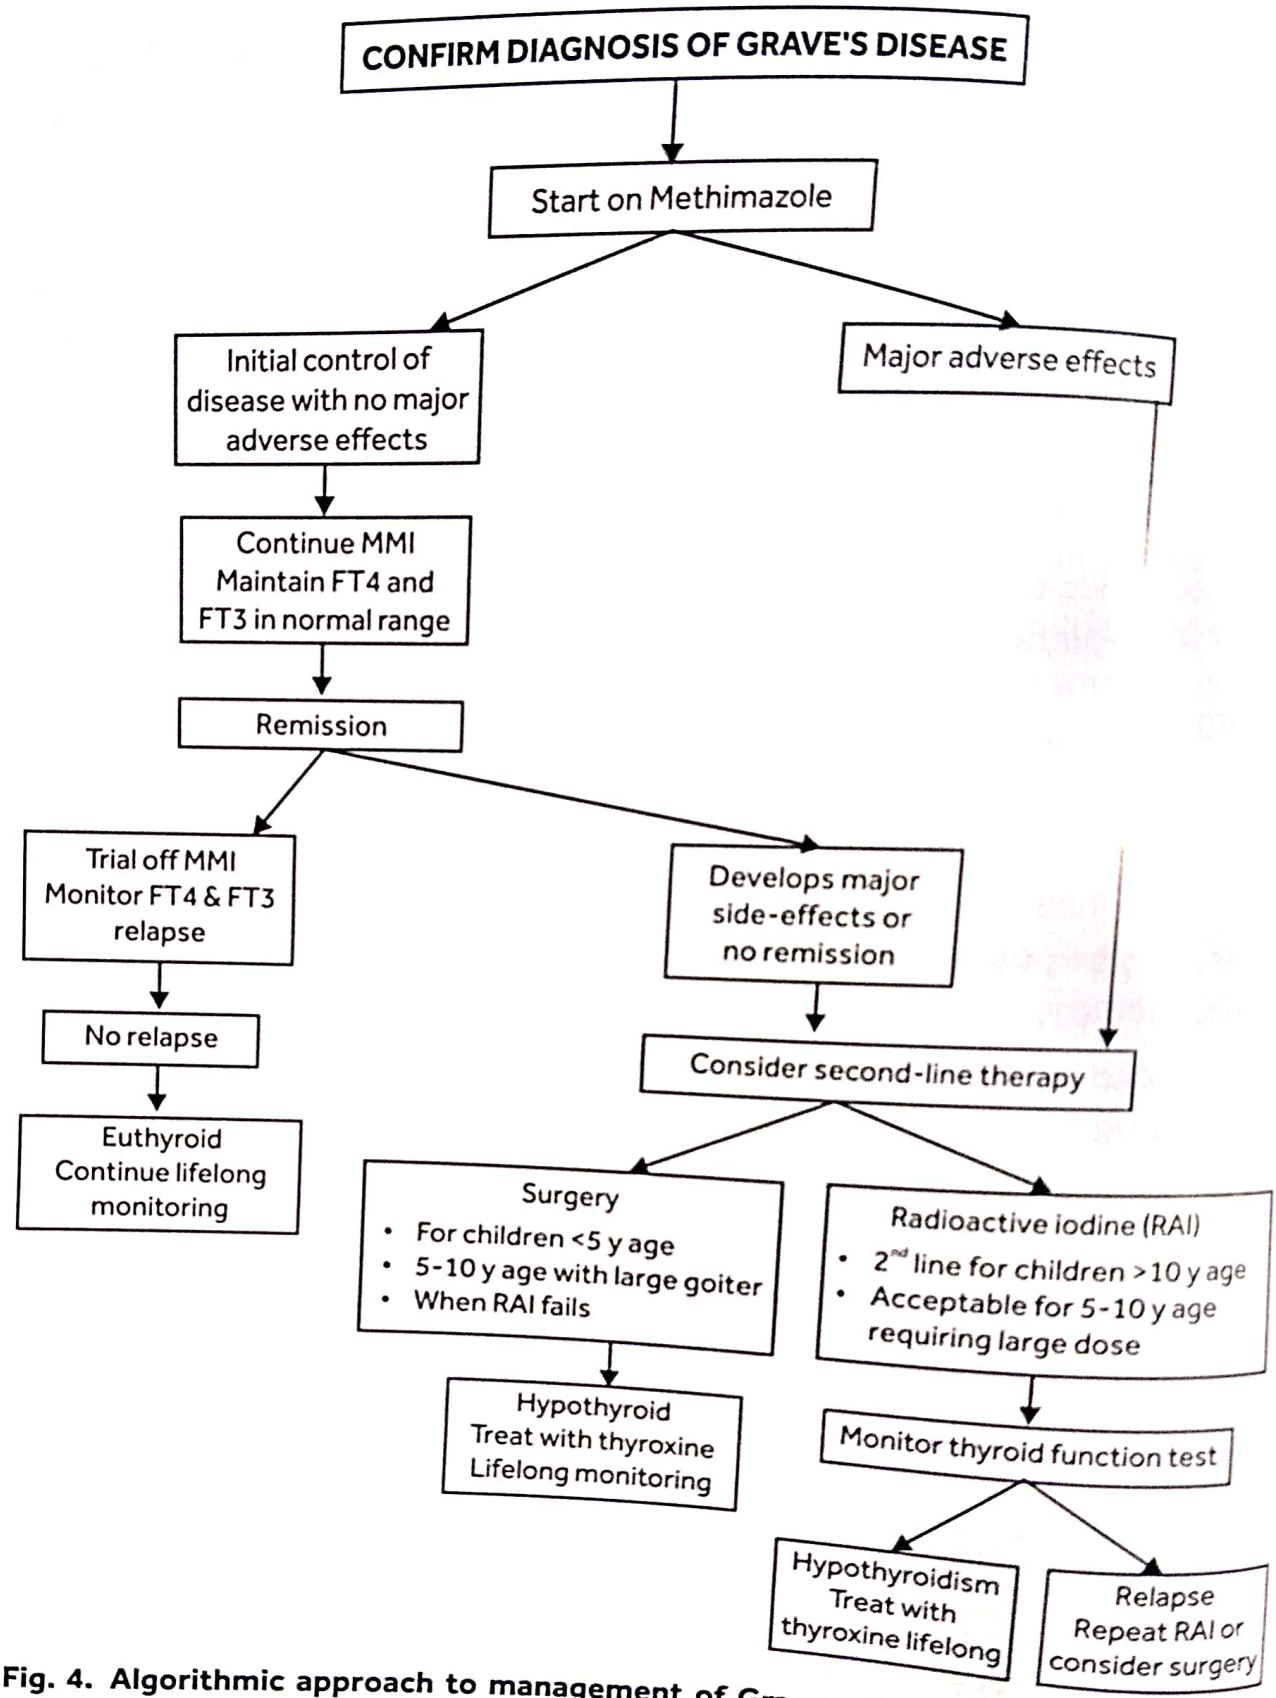

Fig. 4. Algorithmic approach to management of Graves disease.
MMI Methimazole

- Remission of hyperthyroidism is assessed in children at around 3 y of age and if the dose requirement is low in the range of 2.5 to 5 mg per day, a trial off MMI is given.

- Further monitoring is done as shown in the algorithm and if the trial fails, child can be restarted on MMI or definite therapy with RAI or surgery can be offered.

Prognosis

- Remission rate in children with Graves disease varies from 25 to 65 percent.
- Lower thyroid hormone concentrations at presentation, older age and euthyroid status at three months of ATD therapy are the predictors of remission.
- Definite therapy is needed in children who have adverse effect with ATD therapy or if relapse occurs and when a definite therapy is chosen by the patient/family.
- Life-long monitoring is needed for hypothyroidism when RAI is used or surgery is performed.

Neonatal Graves Disease

- It is seen in a small percentage of infants who are born to mothers with Graves disease.
- Graves disease in the mother can lead to hyper or hypothyroidism in the fetus and neonate depending on balance of the maternal inhibitory and stimulatory antibodies and ATD drugs.
- Neonates who are supposed to develop Graves disease are almost always hyperthyroid at or within a week of birth.
- In neonatal Graves disease there is a transplacental passage of maternal stimulatory antibodies (TSH-R-Ab).
- Serial measurement of in-utero ultrasonography of fetal thyroid size can be useful in manifesting neonatal hyperthyroidism. However, one must be careful in interpreting a fetal goiter as it might be seen in both hypothyroidism or hyperthyroidism.
- By 3-12 wk, neonatal Graves hyperthyroidism gets resolved as maternal TSH-R-Ab is metabolized and disappears from the infant's circulation.
- Rarely, neonatal hyperthyroidism is due to activating germline mutations of the TSH receptor or activating mutation of the alpha subunit of the G protein that stimulates adenylate cyclase.

- Clinical manifestations include — intrauterine growth restriction small for gestational age, premature birth, microcephaly, front bossing, triangular facies, warm and moist skin, hyperthermi irritability, wakefulness, hyperactivity, poor sleep, tachycardia, cardia arrhythmia, heart failure, hyperphagia but poor weight gain, increase bowel frequency, diffuse goiter (usually small occasionally can compres airway), stare and occasional exophthalmos.
- The algorithmic evaluation is shown in *Fig. 5*.

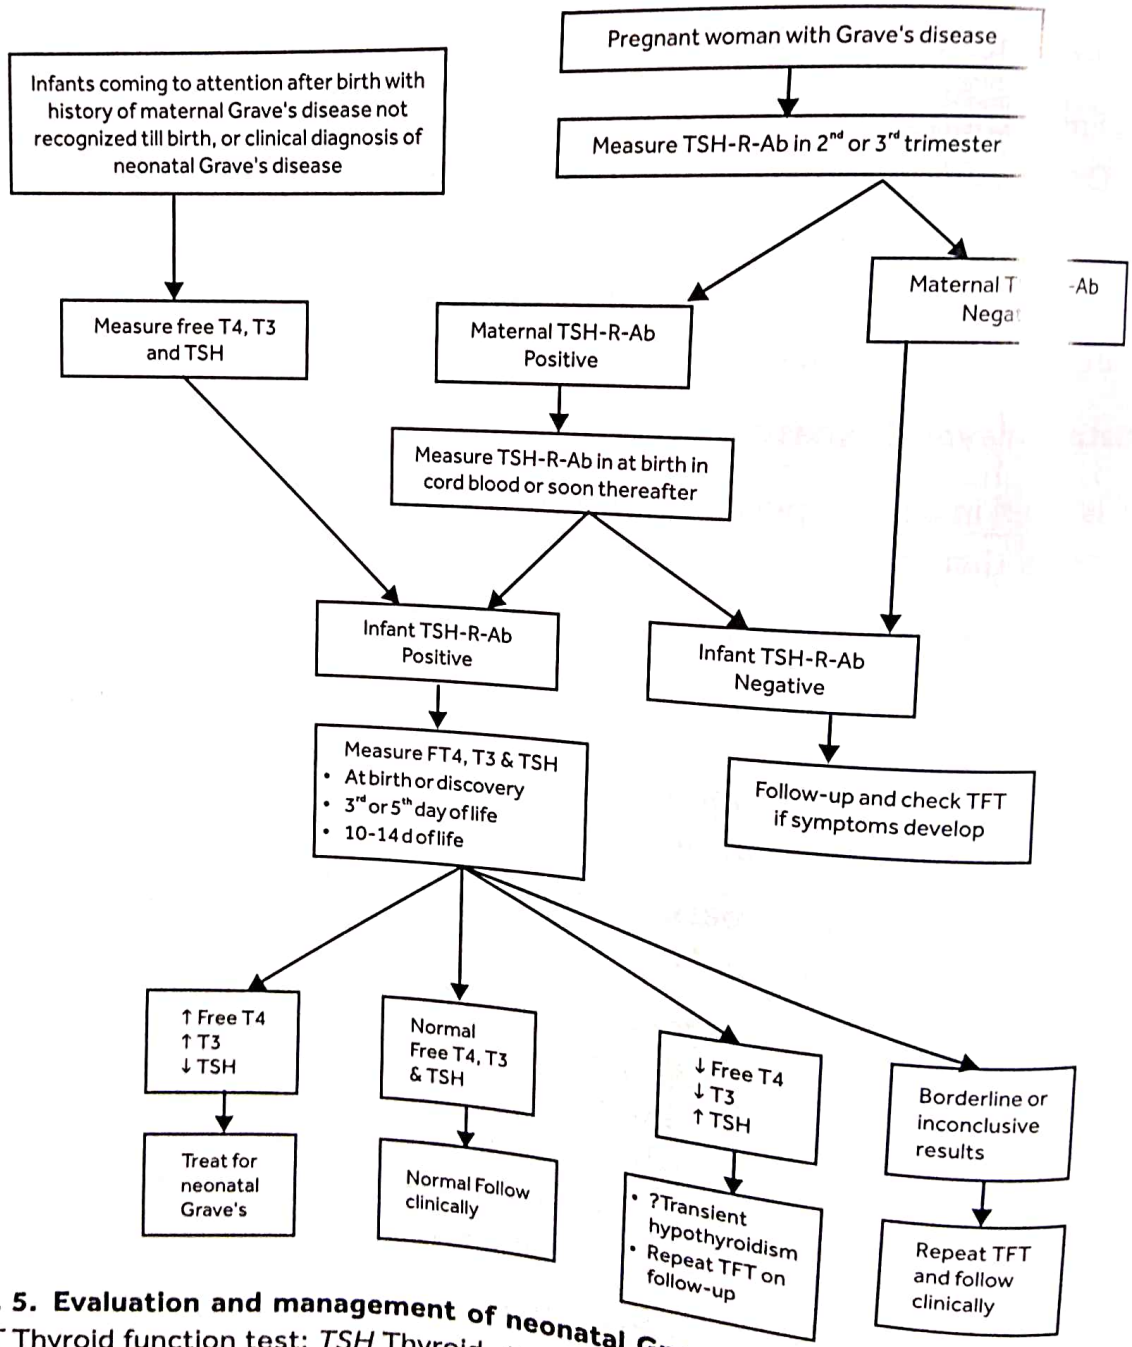

Fig. 5. Evaluation and management of neonatal Graves disease. *TFT* Thyroid function test; *TSH* Thyroid stimulating hormone; *TSH-R-Ab* TSH receptor antibodies

- Methimazole and Propranolol are used for the treatment in neonates.
- Iodine may be added in neonates who are not controlled with MMI and Propranolol.
- Glucocorticoids can be given in extremely ill neonates.
- Prompt diagnosis, early work-up and treatment leads to rapid improvement.
- It should be noted that neonatal Graves disease can be caused by maternal antithyroid drugs or by thyroid stimulating antibodies which cross the placenta. The antithyroid drugs can cause initial hypothyroidism followed by thyrotoxicosis due to the stimulating antibodies. This necessiates estimation of thyroid function at 2 to 3 wk of life in infants of Graves mother.

CASE VIGNETTES

Case 1: *A 14-y-old girl presented with weight loss and irritability.* On examination she had a large goiter with prominent eyes. Thyroid function test (TFT) showed fT4 of 40 pg/ml and TSH was undetectable. TSH-R-Ab was positive. Thyroid scan showed diffusely increased uptake of tracer. All the above findings are suggestive of Graves disease.

The girl was started on Methimazole and was asked to follow-up. She developed fever and sore throat about three weeks later and was investigated. Complete blood count (CBC) showed leukopenia with neutrophilic predominance. Methimazole was stopped and she was treated with oral antibiotics. Methimazole was restarted when symptoms subsided and CBC showed improvement.

Learning Points

- Graves disease should be considered in children with classical history, eye signs and goiter.
- Thyroid scan shows uniformly increased uptake of tracer.
- Methimazole is the drug of choice in children.
- Agranulocytosis should be considered in children on Methimazole with symptoms of sore throat.
- Antithyroid treatment should be temporarily withheld during the period of illness.

Case 2: *A 12-y-boy presented with history of tremors and weight loss for one month.* On examination he had no goiter or classical eye signs. BP was normal. TFT showed free T4 of 32 pg/ml with a low TSH (<0.03). Thyroid scan showed reduced uptake of tracer. The above findings are suggestive of thyroiditis.

Learning Points

- Thyroiditis should be considered in the setting of thyrotoxicosis with no classical eye signs and goiter.
- Thyroid scan shows reduced tracer uptake.
- These children can later end up getting hypothyroidism and hence need follow-up.

Case 3: *A six-day-old baby girl who was born to a mother with Graves disease was brought for opinion.* Mother was on anti-thyroid medications. TFT showed high TSH and low free T4 suggestive of hypothyroidism. The baby was asymptomatic. Repeat TFT done on day 16 of life showed low TSH (< 0.02 mU/L) and high free T4 (38 pg/ml).

Learning Points

- Maternal antithyroid drugs can cause transient hypothyroidism in infants which resolves in about two weeks.
- Thyroid function tests should be repeated after day 14 in infants born to mothers with Graves disease to diagnose delayed presentation of congenital thyrotoxicosis.

Subject: Letter of Contribution in Cloherty and Stark's Manual of Neonatal Care, first South Asian Edition

Dear Dr Suryawanshi,

We express heartfelt appreciation to you for contributing to the chapter on Shock in our book *Cloherty and Stark's Manual of Neonatal Care, first South Asian Edition*, edited by Dr Naveen Jain, Senior Consultant, Department of Neonatology, KIMS Health, Trivandrum, Kerala India.

Your contribution to the book has been significant and aids us to serve the information needs of the scientific community, clinicians, and students with publications of high-quality content and services in health sciences. We recognize the value of your time and efforts to submit thoughtful contributions for the successful publication of the book.

Thank you for considering and trusting Wolters Kluwer as the publication platform for contributing your valuable work.

Sincerely,

Sangeetha Parthasarathy

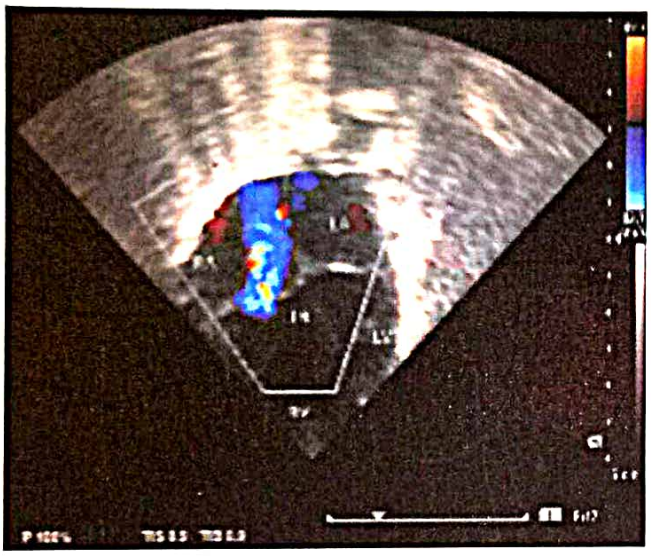
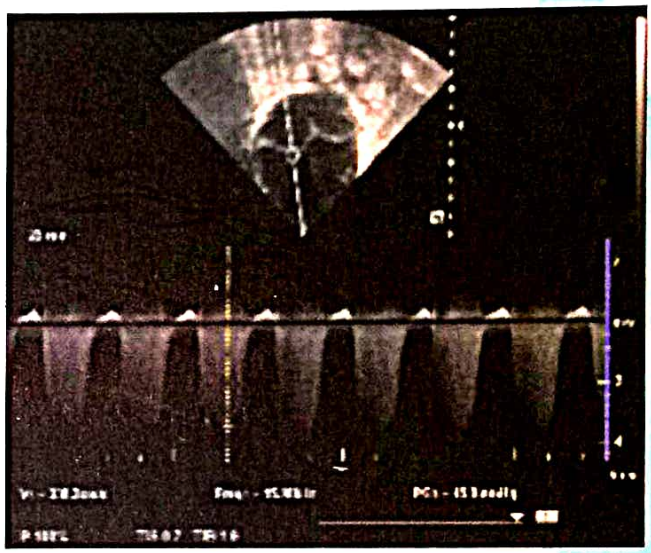
Atlas of Neonatal Functional Echocardiography





Editor-In-Chief
Pradeep Suryawanshi

Editors
Rema Nagpal
Kunal Ahya

Pradeep Suryawanshi

Highlights

Atlas of neonatal functional echocardiography is a practical handbook for neonatal health care providers, post graduates, clinical fellows, pediatricians and neonatologist, covering topics related to functional echocardiography

Salient Features

Basic's of ultrasound machine
How to buy machine
Systemic approach for doing fECHO
Diagnosis and monitoring of various illness

Dr. Pradeep Suryawanshi is one of India's renowned senior neonatologists, currently based in Pune. He earned his MBBS from SBHGMC Dhule and MD Pediatrics from B.J. Medical College, Pune in the year 2000. He subsequently did his DCH and Fellowship in Neonatal Perinatal Medicine from University of Sydney, Australia from 2001 to 2007.

Throughout his academics, he was a meritorious student and a university topper with many feathers in his cap; he has been awarded many gold medals and distinctions. During his tenure in Australia, he received extensive training in neonatal functional Echocardiography & point of care neonatal ultrasound. Taking this forward to future generations, he is a pioneer in introducing functional Neonatal Echocardiography and Point of Care Neonatal Sonography in India.

Dr. Suryawanshi has received laurels from across the country for maintaining the highest standards of care in neonatal intensive care management. His diligence in his work and competence in procedural skills are unmatched. His unprecedented leadership qualities and enthusiastic teachings to his students continue to inspire all around him. He has made an immense contribution in making ultrasound as a bedside simple tool for appropriate early intervention in newborn care.

Presently, he is a Professor and Head of Neonatology at Bharati Vidyapeeth University Medical College, Pune and Head of Neonatology at Sahyadri Hospital, Pune and Noble Hospital, Pune. He is mentor for Department of Pediatrics at BLDE University Bijapur. He is also mentor at various hospitals all across the country (Satara, Kolhapur, Pandharpur, Karad, Jalgaon, Solapur, Barshi, Nagar and Indore). He is a dignified national faculty and Past Secretary of the Maharashtra chapter of the National Neonatology Forum (NNF). He has been awarded many regional and national awards for his excellent work and contributions to the field of newborn resuscitation.

He is the Chief Editor of nationally recognised text books: Point of Care Neonatal Ultrasound & Neonatal Cardiology, Neonatal fEcho made easy, Newer insights in Perinatology, Atlas of POC Neonatal Cranial Ultrasound and Point of care Neonatal Lung Ultrasound. He is also a prime author of many chapters of national and international books and has authored many great articles, presentations and free papers in various journals all across the world.

Dr Suryawanshi has organised several high quality National and International conferences related to Neonatal Haemodynamic and point of care ultrasound and thus providing CME opportunity for many Paediatricians and Neonatologists. Dr Suryawanshi has made an outstanding contribution to pioneering Point of Care Neonatal Ultrasound, conducting 52 workshops nationally throughout India to train colleagues in this modality. He has been instrumental in conducting 92 Neonatal resuscitation workshops and 13 Perinatology workshops in Maharashtra state of India.

Bharati medical college is running successful DM Neonatology & fellowship courses (Bharati fellowship, Indian academic of Pediatrics fellowship & National Neonatology Forum Fellowship) in the neonatal intensive care unit under his guidance and supervision. Above all, he is a true mentor and an embodiment of courage, positivity and exuberant energy for all his students/fellows who are successfully running level III neonatal intensive care units all across the country.

He has been conferred the 2018 award of Fellowship of National Neonatology Forum (FNNF) and also International membership of Neonatologist Performed Echocardiography (NPE) by European Society of Pediatric Research. He has been conferred 2019 award of "FRCPCH" (Fellow of Royal College of Pediatrics and Child Health) by The Royal College of Pediatrics and Child Health, UK, in the year 2019.

Point of Care Neonatal Lung Ultrasound

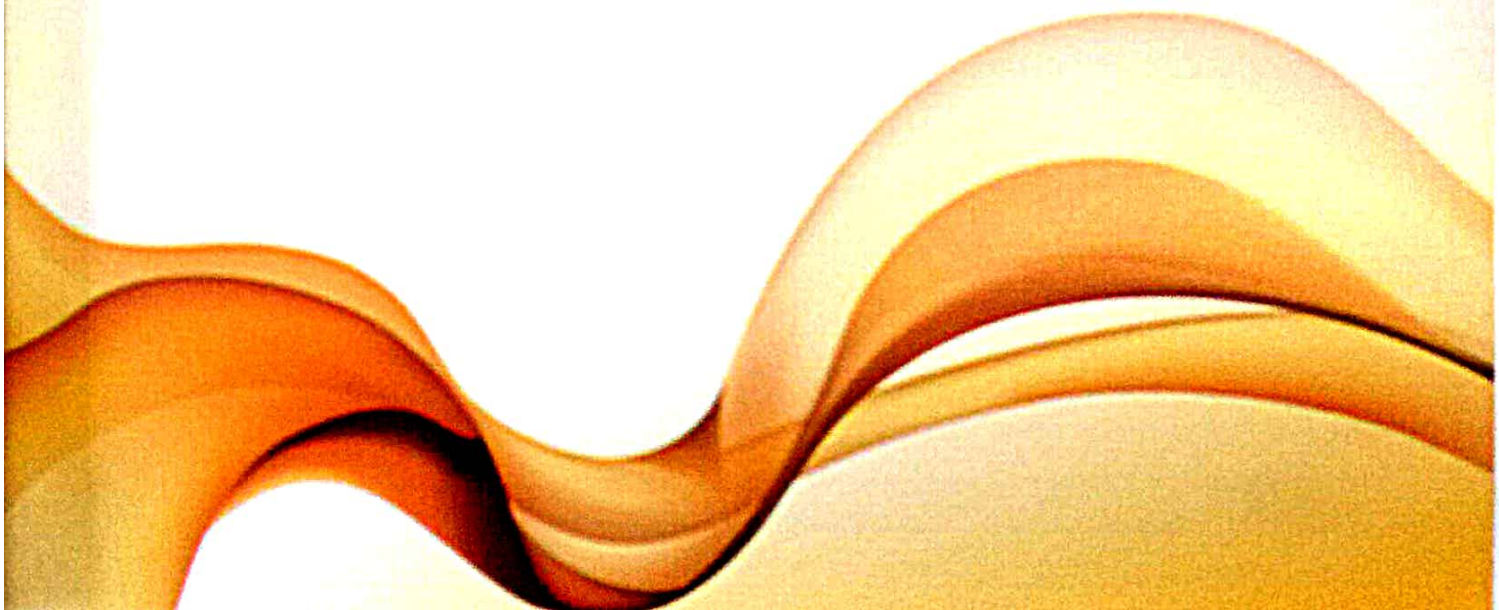
Jan Klimek

Point of Care Neonatal Lung Ultrasound

Pradeep Suryawanshi

Jan Klimek



Highlights

Point of care neonatal lung ultrasound is a practical handbook for neonatal health care providers – Post graduates, Clinical Fellows, Pediatricians, & neonatologist covering common images in the field of point of care neonatal lung ultrasound.

Salient Features

Covers over 100 images
Basic technique of lung ultrasound
Important ultrasound findings
Easy to read & follow

Dr. Pradeep Suryawanshi is one of India's renowned senior neonatologists, currently based in Pune. He earned his MBBS from SBHGMC Dhule and MD Pediatrics from B.J. Medical College, Pune. He subsequently did his DCH and Fellowship in Neonatal Perinatal Medicine from University of Sydney, Australia from 2001 to 2007.

Throughout his academics, he was a meritorious student and a university topper with many feathers in his cap; he has been awarded many gold medals and distinctions. Dr Suryawanshi has organised several high quality National and International conferences related to Neonatal Haemodynamics and Point of care ultrasound. Dr Suryawanshi has made an outstanding contribution to pioneering Point of care Neonatal Ultrasound, conducting 42 workshops nationally throughout India.

Bharati medical college is running successful DM Neonatology & fellowship courses (Bharati, IAP & NNF) in the NICU under his guidance and supervision. Above all, he is a true mentor and an embodiment of courage, positivity and exuberant energy for all his students/fellows who are successfully running level III NICU all across the country.

He has been conferred the 2018 award of Fellowship of National Neonatology Forum (FNNF) and also International membership of Neonatologist Performed Echocardiography (NPE) by European Society of Pediatric Research. He has been conferred 2019 award of "FRCPCH" (Fellow of Royal College of Pediatrics and Child Health) by RCPCH, UK, in the year 2019.

Dr Jan Klimek is a Senior Staff Specialist Neonatologist, currently employed by Westmead Hospital, Sydney, Australia.

Qualifications include MB, ChB, DA, DCH, MRCPCH, FRACP and CCPU (Neonatal).

Dr Klimek started his neonatal ultrasound journey in 1999 and 2000 under the tutorship of the late Dr Rex Betheras in the days when all neonatal ultrasounds were still firmly in the hands of radiologists and cardiologists. After the acquisition of the skills required for neonatal ultrasonography, Dr Klimek helped to provide a service of on-call cardiac ultrasound in Christchurch, New Zealand's South Island, which was then geographically isolated from the Pediatric Cardiology support offered in Auckland. During his three year period at this location, he set up regular fortnightly review meetings with the visiting cardiologists from Auckland, thus fine-tuning his skills and furthering his education in this field.

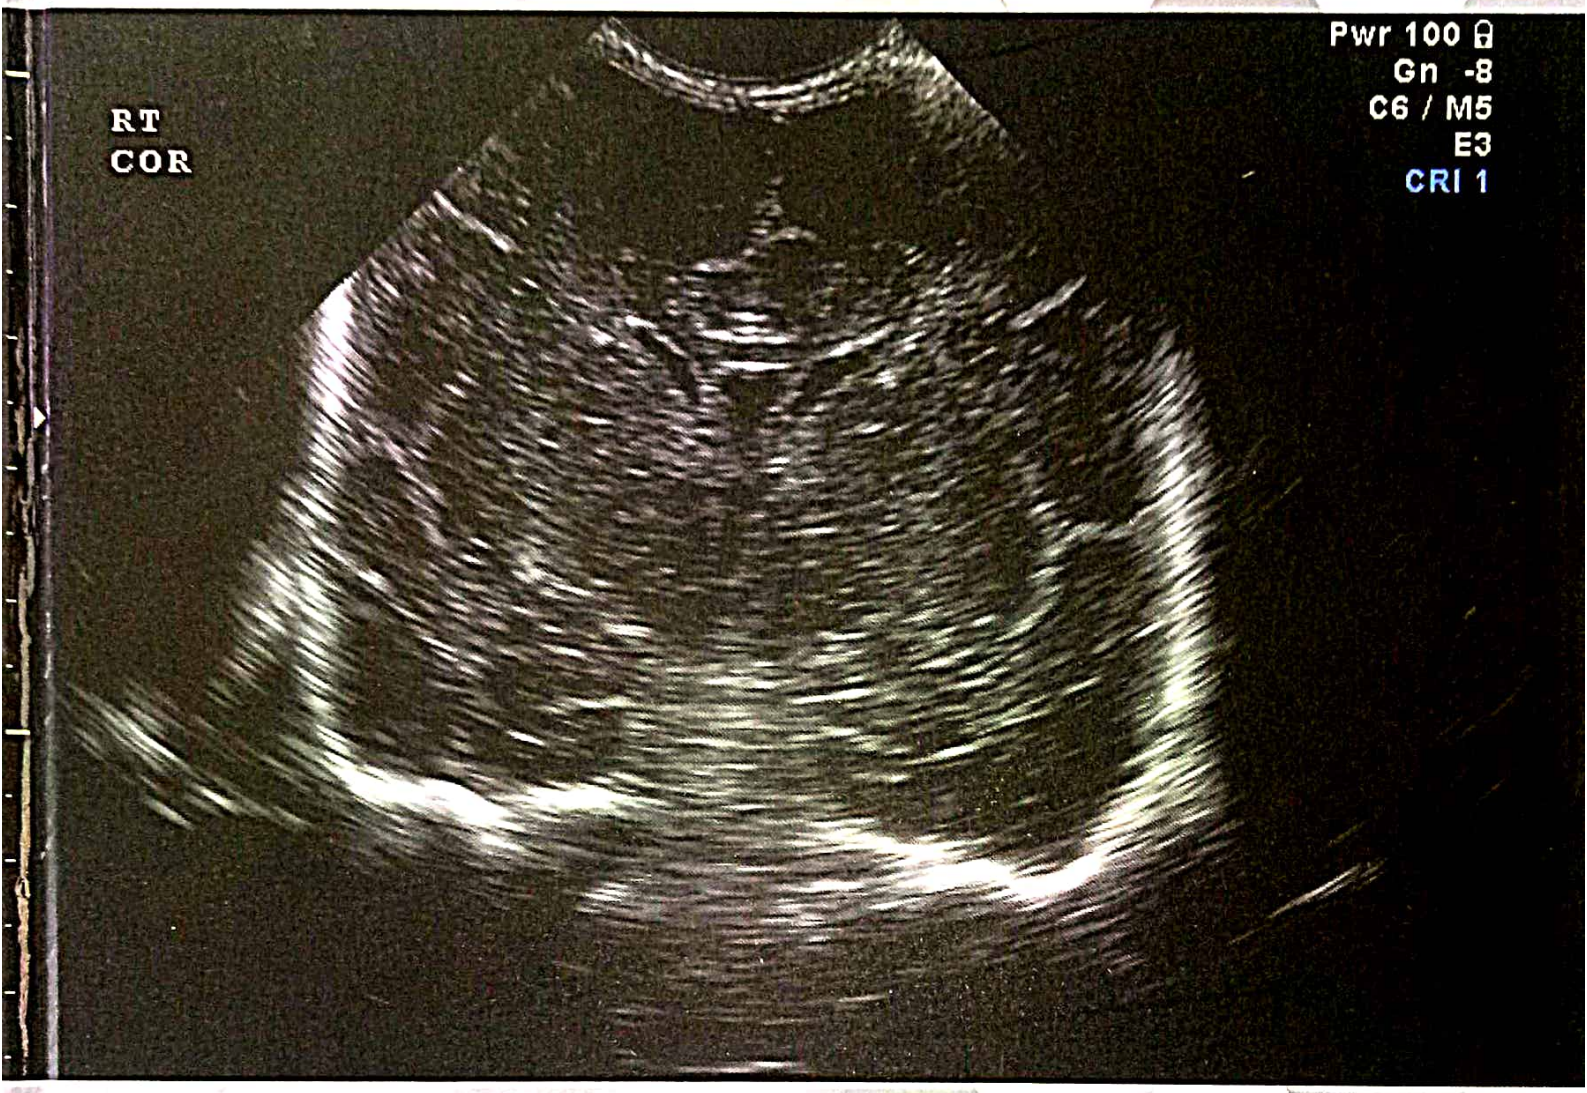
On returning to Australia, he started teaching his ultrasound skills and knowledge to neonatal trainees; the then-doctor (now Professor) Suryawanshi notably one of his first students.

With the advent of the growth of "Neonatal Ultrasound" and the Australian Society of Ultrasound in Medicine (ASUM) creating the category of a Certificate of Clinician Performed Ultrasound (CCPU), Dr Klimek was awarded the CCPU as a teacher in 2009. Dr Klimek then set up the basic CCPU course at his hospital; this still functioning today. He has been accepted as part of the national ASUM CCPU Committee since November 2018.

Today, Dr Klimek works in a neonatal unit together with currently five colleagues who hold the CCPU (Neonatal) and seven CCPU trainees at different levels of experience. Dr Klimek has been the primary neonatologist in this unit as regards CCPU teaching. He has had a number of trainees to date awarded with the CCPU (Neonatal). The neonatal unit is actively involved in performing and reviewing ultrasounds, with a regular fortnightly departmental review meeting. The neonatal unit is involved in a number of ultrasound-related projects and runs an annual basic neonatal CCPU course (since 2016) which satisfies the ASUM certification criteria.

Aside from his clinical duties as a Neonatologist, Dr Klimek also co-ordinates the neonatal Medical Student teaching. He has been awarded "Best Teacher" and "Excellence in Teaching" prizes at both hospitals he has worked in in NSW, Australia. He is a co-author in 10 publications.

Atlas of Point of Care Neonatal Cranial Ultrasound



Pradeep Suryawanshi

Atlas of Point of Care Neonatal Cranial Ultrasound

Pradeep Suryawanshi

Pradeep Suryawanshi

An Atlas of point of care neonatal cranial ultrasound is a practical handbook for neonatalhealth care providers – Post graduates, Clinical Fellows, Pediatricians, & neonatologist covering common images in the field of point of care neonatal cranial ultrasound.

Salient Features

Covers 400 images
Basic technique of cranial ultrasound
Important ultrasound findings
Easy to read & follow

Dr. Pradeep Suryawanshi is one of India's renowned senior neonatologists, currently based in Pune. He earned his MBBS from SBHGMC Dhule and MD Pediatrics from B.J. Medical College, Pune in the year 2000. He did his DCH and Fellowship in Neonatal Perinatal Medicine from University of Sydney, Australia from 2001 to 2007.

Throughout his academics, he was a meritorious student and won many accolades. During his tenure in Australia, he received extensive training in neonatal functional Echocardiography & point of care neonatal ultrasound. Taking this forward to future generations, he is a pioneer in introducing functional Neonatal Echocardiography and Point of Care Neonatal Sonography in India.

He has received laurels from across the country for maintaining the highest standards of care in neonatal intensive care management. His diligence in his work and competence in procedural skills are unmatched. His unprecedented leadership qualities and enthusiastic teachings to his students continue to inspire all around him. He has made an immense contribution in making ultrasound as a bedside simple tool for appropriate early intervention in newborn care.

Presently, he is a Professor and Head of Neonatology at Bharati Vidyapeeth University Medical College, Pune and a Head of Neonatology at Sahyadri Hospital, Pune and Noble Hospital, Pune. He is mentor for Department of Pediatrics at BLDE University Bijapur. He is also mentor at various hospitals all across the country (Satara, Kolhapur, Pandharpur, Karad, Jalgaon, Solapur, Udaipur, Barshi and Indore). He is a dignified national faculty and Secretary of the Maharashtra chapter of the National Neonatology Forum (NNF). He has been awarded many regional and national awards for his excellent work and contributions to the field of newborn resuscitation. He is the main author of Point of Care Neonatal Ultrasound and Neonatal Cardiology, which is the first book in India in this field. He is also a prime author of Newer Insights in Perinatology. He has authored many articles, presentations and free papers in various journals all across the world.

Currently Bharati medical college is running successful DM Neonatology & fellowship courses (Bharati fellowship, Indian academic of Pediatrics fellowship & National Neonatology Forum Fellowship) in the neonatal intensive care unit under his guidance and supervision.

Inspired by his positivity and exuberant energy, his guidance has helped many of his students/fellows to pursue oversea experience in neonates and also to run successful level III neonatal intensive care units all across the country.

Subarachnoid Hemorrhage

29

Shiva Kumar Iyer, Jignesh Shah, and Kiran Vadapalli

A 24-year male cricket player complained of sudden headache followed by a brief period of loss of consciousness while playing. On arrival at the emergency department, he was drowsy but answering questions and reported that he had the worst headache ever. Examination revealed a blood pressure of 150/62 mm Hg and has neck stiffness. Rest all neurological examination was unremarkable. He does not give any significant past history and denies any trauma or addictions. Emergency noncontrast CT head revealed diffuse subarachnoid hemorrhage occupying the basal cisterns and bilateral Sylvian fissures.

Subarachnoid hemorrhage (SAH) should be suspected in patients presenting with acute onset severe headache which they classically describe as the worst headache of their life. Most subarachnoid hemorrhages (SAH) are caused by rupture of intracranial saccular (berry) aneurysms. Other causes include trauma, vascular malformations, hemorrhagic infarctions and hypertensive hemorrhages.

Risk factors include cigarette smoking, hypertension, estrogen deficiency, coarctation of the aorta, hereditary diseases like polycystic kidney disease and Ehler-Danlos syndrome. The high morbidity and mortality associated with aneurysmal SAH (aSAH) mandate a high degree of suspicion to allow timely and appropriate treatment.

Step 1: Start Resuscitation

- Emergency airway protection is necessary for obtunded patients to avoid hypercarbia and rise in intracranial pressure. Indications for endotracheal intubation include a Glasgow Coma Scale (GCS) score ≤8, elevated intracranial pressure (ICP), hemodynamic instability, poor oxygenation or hypoventilation and requirement for heavy sedation or paralysis.

Coma

32

Kayanoosh Kadapatti and Shiva Kumar Iyer

A 30-year-old male patient, who was found unconscious in his room, was brought to the emergency department. On examination, he was found to be tachypneic and febrile with normal blood pressure. He was not opening his eyes and was withdrawing arms on pain.

The comatose patient in the ICU poses a diagnostic and therapeutic challenge to the physician. A broad range of differential diagnoses necessitate a systematic approach and judicious use of investigation in these patients.

Step 1: Assess and Stabilize the Patient

- In any unexplained coma, caution should be taken to avoid cervical spine movement while managing airway.
- Intubate if GCS <8
- If there is hypoglycemia (<60 mg/dL), it should be urgently corrected with 50 mL of 25% dextrose intravenously.
- Thiamine 100 mg IV should be given prior to glucose to avoid Wernicke's encephalopathy, especially in patients with malnutrition and alcoholism.
- Control seizure, if present, with intravenous lorazepam.
- In patients who show features of increased intracranial pressure (ICP), 100 mL of 10% intravenous mannitol should be given (see Chap. 33, Vol. 1).
- Give prompt antibiotics in patients with signs suggestive of meningitis.

Acute Febrile Encephalopathy

34

Jignesh Shah and Shiva Kumar Iyer

A 40-year-old male patient was admitted to hospital with a 2-day history of fever, headache, and increasing confusional state. He was protecting his airway, had a respiratory rate of 22/min with an oxygen saturation of 95% and was febrile without hypotension. On neurological evaluation, he was disoriented to time and place, was opening eyes on verbal command, had an incomprehensible speech, and was moving all limbs spontaneously. He had neck stiffness and fundi were normal.

A high index of suspicion should be maintained for a diagnosis of an infection involving the nervous system in any patient with fever and altered mental state. Time is essence in managing these patients as any delay could lead to irreversible brain damage (Fig. 34.1).

Step 1: Initiate Resuscitation and Assess Neurological Status

- In patients with neurological problems, assessment of airway and need for intubation is of paramount importance as these patients are at high risk of aspiration. Glasgow coma scale (GCS) below 8 usually requires airway protection (see Chap. 23, Vol. 2).
- Maintenance of adequate oxygenation and perfusion are equally important for preventing secondary brain injury.
- Checking the blood sugar level, arterial blood gases with electrolytes will help identify additional immediate priorities for resuscitation

JAYPEE

Contents

Section 1: Respiratory/Airway/Ventilation

Section Editors: *Harjit Dumra, Suresh Ramasubban*

1.1. Use of High-flow through Nasal Cannula to Prevent Extubation Failure 3
Supradip Ghosh, Ripenmeet Salhotra

1.2. Predictors of High-flow Nasal Cannula Failure in Intensive Care Unit 8
Rajesh Chawla, Prashant Nasa, Aakanksha Chawla Jain

1.3. Oxygen Therapy in ICU: Evolving Practices, Newer Evidence and Deeper Insights 13
Farhad Kapadia, Pandurang Tekawade

1.4. Practice Changing Updates in Airway Management in Critically Ill Patients 18
Syed Moied Ahmed, Manazir Athar

1.5. Tidal Volume and Driving Pressures on Noninvasive Ventilation 26
Vijay Hadda, Arun Raja

1.6. Upper Extremity Deep Vein Thrombosis 30
Asif Ahmed, Mahajyoti Chakravorty, Subhendu Mishra

1.7. Driving Pressure-guided Ventilation in Acute Respiratory Distress Syndrome 35
Dhruva Chaudhry, Mansi Gupta, Manjunath BG

1.8. NIV Asynchrony: How to Overcome? 41
Suresh Ramasubban

1.9. When to Select Pressure-control and Volume-control Mode of Ventilation in Acute Respiratory Distress Syndrome 45
Sachin Gupta, Deeksha Singh Tomar

1.10. Assessment of Respiratory System Mechanics at Bedside in a Mechanically Ventilated Adult Patient 48
Rupak Kundu, Subhash Todi

1.11. Pleural Effusion and Its Impact on Weaning 55
Manish Munjal, Parshotam Lal Gautam, Nikhil Kothari

1.12. Recent Trials from PETAL Network 59
Ajeet Singh, Shrikanth Srinivasan, Vel Murugan, Manali Patel

1.13. Phenotype in Acute Respiratory Distress Syndrome 61
Rajesh Pande, Trishala Singhvi, Maitree Pandey

1.14. Low-dose Thrombolytics in Massive Pulmonary Embolism: Whether Less is More? 65
Inderpaul Singh Sehgal, Sahajal Dhooria, Ritesh Agarwal

1.15. Pneumonia Panel: Will it be Useful in ICU? 68
Karuna Tiwari, Camilla Rodrigues

Section 2: Cardiovascular/Hemodynamics/Cardiopulmonary Resuscitation

Section Editors: *Sheila Nainan Myatra, Sameer Jog*

2.1. Balanced Crystalloids: Is the Evidence Getting Stronger? 73
Natesh Prabu R, Atul Prabhakar Kulkarni

2.2. Liberal Fluid Resuscitation versus Early Vasopressors in Septic Shock 79
Jose Chacko

Section 9: Quality/Organization/Safety/Research

Section Editors: *Banambar Ray, Srinivas Samavedam*

9.1. Communication Skills in ICU 389
Banambar Ray, Janmejay Nayak

9.2. Use of Artificial Intelligence in Intensive Care Unit 393
Goverdhan D Puri, Rajarajan Ganesan

9.3. Battling Burnout in ICU 400
Sumit Ray, Saurabh Kumar Das

9.4. Critical Care Outreach Team 407
Yash Javeri, Ravi Jain, Sandesh Kumar

9.5. Out of Hours and Weekend Admission/Transfer from ICU 415
Girish Agrawal

9.6. Important Time Windows in Managing Critically Ill 417
Meghena Mathew, Nagarajan Ramakrishnan

9.7. Family-centered Care: How to Achieve it? 422
Babu K Abraham

9.8. Improving Organ Donation in ICU 427
Rohit Yadav, Yash Javeri, Preeti Bhadauria

9.9. Geriatric Critical Care Complexities 435
Anuj M Clerk, Krunal J Patel

9.10. Optimizing Intensive Care Unit Alarm 442
Diptimala Agarwal, Kanwalpreet Sodhi, Vivek Badada

9.11. Communication in the Intensive Care Unit 446
Shivakumar Iyer

9.12. External Validity of Intensive Care Unit Trials in Resource Limited Settings 452
John Victor Peter

9.13. Conducting Multidisciplinary ICU Rounds 456
Prakash Shastri, Prasoon Gupta

9.14. Readmission in ICU: Quality Indicator 459
Devi Prasad Samaddar, Arindam Mukherjee, Dibyadip Mukhopadhyay

9.15. Bringing Precision Medicine to Bedside 463
Pavan Kumar Reddy N, Venkat Raman Kola

9.16. Simulation in Intensive Care 467

CHAPTER 9.11

Communication in the Intensive Care Unit

Shivakumar Iyer

"The single biggest problem in communication is the illusion that it has taken place".

George Bernard Shaw

INTRODUCTION

Communication in the intensive care unit (ICU) has been rated as one of the important concerns by family members of patients admitted in the ICU.[1] Families rely on honest and accurate information about the disease process and its likely course for decision-making in the ICU. Unfortunately, the evidence suggests that healthcare providers are found wanting in this regard. Observational studies indicate that up to one-third of family members are not happy with communication in the ICU.[2]

The factors that have been implicated include inadequate time given, lack of consistent information, and conflicting information by healthcare providers. Poor communication has been shown to affect family satisfaction, clinical decision-making, and psychological outcomes of family members.[3] Family dissatisfaction may manifest as anger, violence, and litigation which results in greater stress and burnout in healthcare providers. Many strategies have been suggested in order to improve family satisfaction in ICU.[4]

PRINCIPLES OF COMMUNICATION

The root of the word communication from Latin is "communicare" which means to share or receive. Communication can be defined as "a process by which information is exchanged between individuals through a common system of symbols, signs, or behavior".[5] Good communication therefore requires a shared verbal language and an understanding of the components of nonverbal behavior. Both these components are also culturally and geographically determined and will therefore vary from place to place. Nonetheless, there are certain common principles of good communication.

The four principles elucidated by the I Medicine Committee on Quality of Health Care are:

1. Obtaining and grasping the patient's viewpo
2. Taking into account the patient's psychologic social reality
3. Arriving at a joint understanding of the patie problem and looking at solutions in the co patient's preferences and values
4. Respecting patient's autonomy and empo patient through shared decision-making.[6]

Workbook on Renal Replacement Therapy in ICU

by Sunitha Binu Varghese, Valentine Lobo, Jignesh N Shah

This workbook focuses on renal replacement therapy in ICU. The incidence of acute kidney injury in critically ill patients is increasing steeply. Acute kidney injury in this setting is associated with high morbidity and mortality. There is no doubt that renal replacement therapy for the most severe forms of acute kidney injury can be life saving. The objective of this synthetic review is to present current evidence supporting best practices in renal replacement therapy for critically ill patients with acute kidney injury. This book consists of 19 chapters, which include acute kidney injury, biomarkers in acute kidney injury, renal replacement therapy: nomenclature and terminology, indications and timing of RRT in AKI, anticoagulation on RRT, acute peritoneal dialysis in critical care, chronic kidney disease patient in ICU, drug dosing on renal replacement therapy, extracorporeal therapies in sepsis, extracorporeal therapies in poisoning, nutrition for acute kidney

CLINICAL APPLICATION OF VIDEO HEAD IMPULSE TEST

Anuj Kumar Neupane[1,*] and Sujeet Kumar Sinha[2]
[1]School of Audiology and Speech Language Pathology,
Bharati Vidyapeeth (Deemed to be University), Pune India
[2]Department of Audiology, All India Institute of Speech and Hearing,
Mansagangothri, Mysore, India

ABSTRACT

Video head impulse test (vHIT) is the modern instrumental development in the field of vestibular assessment that uses high acceleration head impulse with light weighted goggles to test all the six semicircular canal [1-3]. This technological development is based on the principle of Head Impulse Test (HIT), which was initially used to examine the vestibulo-ocular reflex pathway in individuals who were unable to give response or in coma. HIT examines vestibulo-ocular reflex pathway wherein the patients are instructed to gaze at the target even while the thrust is given to the head in pitch, yaw, and roll axes. In case of a peripheral vestibular lesion associated with semicircular canal, vestibulo-ocular reflex pathway is affected, which leads to generation of saccades.

* Corresponding Author's Email: anujkneupane@gmail.com

Complimentary Contributor Copy

However, these saccades generated during the head jerk are virtually difficult to observe with naked eyes [4, 5]. Moreover, the traditional head impulse test was done only for lateral semicircular canals, hence the clinicians were not able to know the lesions of the vertical canals.

This inability of HIT is solved by a recent advancement of video head impulse test (vHIT) which works on the same principle as HIT at same amplitude and high acceleration. vHIT can measure overt and covert saccades (which cannot be detected by naked eye). With the brief but high velocity head impulses, vHIT examines all six SCCs separately [6, 7]. The vHIT has been authenticated by simultaneous comparison with the scleral search coil across both the healthy as well as pathological vestibular population such as Meniere's disease [8], vestibular neuritis [9], vestibular migraine [10] and in case of benign paroxysmal positional vertigo [11] with good sensitivity and specificity. A very considerable clinical literature is described by the fact that the well- known caloric test detects the functioning of only two horizontal SCCs at a very low and brief frequency range of around 0.002 to 0.004 Hz which is beyond the frequency range the semicircular canals experience in day to day life [12].

The vHIT has been reported to be beneficial over caloric test in examining various clinical vestibular conditions in children, younger and older adults. vHIT has been found to be useful in diagnosis of lesions of vestibulo ocular reflex pathways in individuals with stroke, vestibular neuritis, peripheral vestibulopathy, Meniere's disease, individuals with BPPV and individuals with auditory Neuropathy Spectrum disorders [9, 13-15].

Keywords: head impulse test, vestibular disorders, vestibular assessment, vestibulo-ocular reflex

INTRODUCTION

HEAD IMPULSE TEST

Vestibular disorders are one of the most common anomalies reported across all age groups which need detailed medical interview, neurological evaluation, physical examination, and vestibular evaluation [16-20]. Moreover, identification of the condition is the most vital in determining its prognosis. However, there is difficulty in categorizing all balance related illness due to the unavailability of appropriate clinical tools in evaluating all

Complimentary Contributor Copy

vestibular end organs and its networks. These vestibular end organs comprise five entities: three semicircular canals i.e., lateral, anterior, and posterior, basically regulating angular acceleration and two otoliths i.e., utricle and saccule, executing linear acceleration. The three-dimensional gaze and postural stability in human are maintained with the help of three primary vestibular reflexes, out of which angular vestibulo-ocular reflex (VOR) helps retaining the stability of gaze by keeping the eye in same velocity but opposite in direction to that of the head rotation. In addition, the six semicircular canals (constituting both sides of the head), arranged in three orthogonal planes, are important for the detection of head movements in three dimensions. Thus, depending on the provision of angular acceleration, coplanar canals (left anterior vs right posterior semicircular canals – LARP, right anterior vs left posterior semicircular canals – RALP, and right horizontal vs left horizontal semicircular canals) present in each side of the head, come into action and function together in push and pull manner [21].

While fixating a subject onto the target, these abrupt impulsive head rotations can be generated with passive head-only impulses by clinician, active head-only impulses by the subject itself, passive head-only impulses by electromechanical rotation and passive whole-body impulses by electromechanical rotation [22-25]. However, the passive head impulses are reported to be a reliable bedside test in comparison to active head impulses which give higher VOR gain and frequent clustered refixation saccades during than after the head rotation. These passive head impulses by clinician are small, brisk, and unpredictable than the active head impulses and are valid procedure for examining the functioning of semicircular canals [4].

Mechanism of Head Impulse Test (Neural to Physiological Response)

Head movements of normal individuals can have high accelerations of more than 4000°/s [26]. It results in a fast onset response with eye movement of about 8ms from the incidence of head movement to fixate the gaze

Complimentary Contributor Copy

accordingly [27]. These head movements result in fluid displacement, giving rise to the deflection of cupula between the coplanar axes of semicircular canals [28]. For example, when the head turns towards right side, it gives rise to the displacement of the hair cells towards kinocilium at horizontal semicircular canals resulting in the depolarization of the right hair cells and therefore, excitation. Similarly, the displacement away from kinocilium results in the hyperpolarization of the left hair cells and inhibition. These variations in the firing rate get diffused along the vestibular nerve followed by the superior and medial vestibular nuclei as well as cerebellum. Excitation results in the transmission of impulses to the oculomotor nuclei through the white matter tracts at brainstem and the activation of right medial rectus muscle (ipsilateral) and left lateral rectus muscle (contralateral). Antagonistically, inhibitory impulses result in the relaxation of right lateral rectus (ipsilateral) and left medial rectus (contralateral) giving rise to the horizontal compensatory eye movements to the left. This quick onset response is the resultant of type I receptors and irregular afferents present at the central area at crest of crista [29].

Similarly, in case of stimulation to the anterior canal, for example, when the head is bent down, excitatory stimulations are transmitted from the labyrinth via ipsilateral superior vestibular nucleus to the superior rectus muscle (ipsilateral) and inferior oblique muscle (contralateral) which are subdivisions of contralateral oculomotor nucleus. Antagonistically, inhibitory impulses result in the relaxation of inferior rectus muscle (ipsilateral) via divisions of ipsilateral oculomotor nucleus and superior oblique muscle (contralateral) via contralateral trochlear nucleus. This gives rise to the upward deflection of both eyes. Likewise, when the head is bent upward, it results in the excitation of the posterior semicircular canal. This gives rise to the excitatory signals from the labyrinth to the inferior rectus (contralateral) via contralateral oculomotor nucleus and superior oblique (ipsilateral) via contralateral crossed trochlear nucleus. However, the inhibitory impulses give rise to the relaxation of the superior rectus (contralateral) via contralateral oculomotor nucleus and the inferior oblique via ipsilateral oculomotor nucleus resulting in downward deflection of both eyes [30].

Complimentary Contributor Copy

Clinical Applications of Head Impulse Test

The HIT can be performed in a well-lit room as there is no need of dark room to subside the visual field. Therefore, with its very abrupt head thrust of more than 150°/s, one can perform a HIT even during the active attacks of vertigo. Moreover, these head impulses are natural stimulators generating angular momentum and thus, the activation of semicircular canals than any other artificial modes of stimulation yet not well understood [31, 32].

Earlier study by Aw et al. reported the presence of saccades when the high velocity head movement was made towards the lesioned peripheral side [33]. This technique is known as Head Impulse Test (HIT), which was originally used to examine bed-ridden or coma patients. Brisk, brief, and unpredictable stimulation of the test is too rapid for assessing oculomotor control systems. Hence, HIT purely examines the VOR reflex pathway wherein the patient is directed to gaze at the target even while the jerk is given to head in pitch, yaw, or roll axis. The central mechanism acts to maintain the gaze in a stationary target with compensatory saccades and the examiners need to be well trained in detecting those saccades with naked eyes.

Limitations of Head Impulse Test

In the HIT, an unpredictable abrupt jerk is given about 15° and therefore, the presence of instantaneous compensatory response is checked, if any. In a healthy individual, for each head thrust given, the eye movement response will compensate in maintaining gaze stability to the target. However, a patient with vestibular dysfunction will not be able to maintain these quick eye responses to the head impulse given and will lead to catch-up saccades at the end of each head jerk. These visible overt catch-up saccades are the clinical sign of canal paresis in these individuals [34].

Nevertheless, the HIT being a subjective test with not any objectifiable record of patient's response, has the major drawback of not able to profile any clinical signs of canal paresis during the test procedure. Parameters such

Complimentary Contributor Copy

as VOR gain, which is ideally considered 1.0 in a healthy adult, will be reduced in patients with vestibular dysfunction along with catch-up saccades. Moreover, some of the catch-up saccades, also known as covert saccades are virtually difficult to detect with naked eyes in HIT, making it clinically less feasible and therefore suggesting the crucial need to have an objective tool to record a fast eye movement response with adequate resolution to understand VOR gain, covert and overt saccades [4, 5]. This imperative requirement is solved with the development of an advanced Video Head Impulse Test (vHIT), which works in the same principle as HIT.

VIDEO HEAD IMPULSE TEST

Ten years of continuous research in the field of vestibular research has come up with a high-tech objective replica of HIT, also known as vHIT. The vHIT system has been recognized as the standard test protocol in understanding the functioning of semicircular canals [3]. It is a quick, innocuous, and easily repeatable test that provides quantitative time series records of all three orthogonal planes of semicircular canals exclusively and therefore, is useful in examining the canals function before and after the intervention [6, 7]. It has been authenticated by simultaneous comparison with the scleral search coil across both the healthy as well as pathological vestibular populations such as Meniere's disease [8], vestibular neuritis [9], vestibular migraine [10] and also in case of benign paroxysmal positional vertigo [35-41].

Over the years, vHIT has been found to have good sensitivity in detecting vestibular loss that ranges from almost normal to complete canal paresis [42, 43]. Moreover, it has disclosed the presence of variations in saccadic timing and pattern that may be associated with the adequacy of vestibular compensation mechanism. Along with overt saccades for maintaining the gaze in the target, some patients may even utilize covert saccades for obscuring retinal slip which could have occurred due to VOR inadequacy [44]. These brief covert saccades can be recorded with vHIT and

Complimentary Contributor Copy

thus, its importance in compensation of vestibular loss can be well understood [45-47].

Instrumentations of Video Head Impulse Test

With laptop running manufacturers' vestibular software, the vHIT can be administered in a regular lit room. Frenzel glasses with clean face cushions need to be tightened aptly to prevent slippage such that the camera can track participants' pupil movement. The vHIT instrument has two laser pointers projected onto the wall, placed at the distance of 1 metre from the participant seated adjustable for calibration. The instrument is calibrated with the instruction to track laser pointer moving alternatively at two targets without the head kept fixed. Once calibrated, participant is instructed to fix the gaze at a target 'dot' even when the head thrust is given to achieve the VOR gain at different planes [3].

The head thrust of around 40 times is often given for each plane (pitch, roll, and yaw planes) in a randomized manner at an angle of 10-20 degrees with peak head velocity of 200°/s and peak acceleration of 2000 to 6000°/s^2. During the testing, head is accelerated sufficiently such that the semicircular canal on the side of stimulation gets excited while the other side leads to inhibition of the afferents. The head impulse in the horizontal axis leads to the stimulation of horizontal semicircular canals. Similarly, when the head is rotated at 45° to the trunk and therefore, the thrust is given downward, it stimulates the anterior semicircular canal lying opposite to the side of rotation. In addition, the thrust given upward stimulates the posterior semicircular canal at the side of rotation [48]. While examining the vertical semicircular canals, participants should fix their eyes to the target kept in front while the thrust is in the plane of the canals being stimulated. The presence of vestibular lacunae with total or partial loss of semicircular canal functioning leads to unmatching of eye velocity curve to that of head velocity and gives rise to corrective saccades i.e., overt and covert saccades to preserve the gaze stability [15, 49-51]. Moreover, one needs to be careful

Complimentary Contributor Copy

in aligning head appropriately before the stimulation as it may affect the VOR gain and corrective saccades [52].

Recording Procedures of Video Head Impulse Test

The vHIT follows two different recording procedures based on the location of target which is moved during the rotation of head or not. They are:

- Head Impulse Protocols (HIMPs)
- Suppression Head Impulse Test Protocols (SHIMPs)

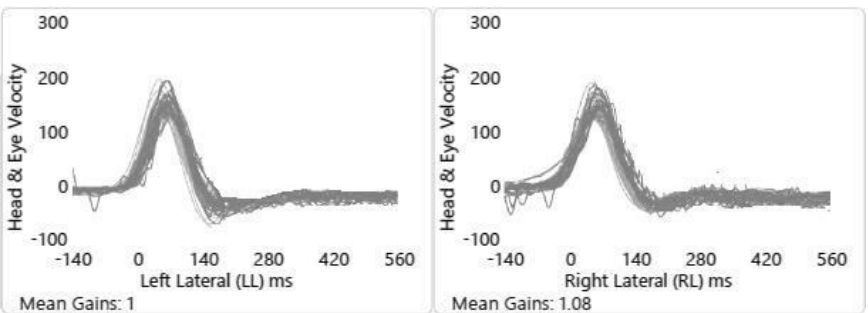

Figure 1. Shows VOR gain in HIMP paradigm in lateral plane.

Head Impulse Protocols (HIMPs)

HIMPs follows the traditional HIT procedure wherein the instruction is given to maintain the gaze at a fixed target spot kept at 1 metre distance on the wall even when the abrupt, unpredictable head thrust is given. HIMPs testing provides absolute data on the functions of semicircular canals which are less credible in caloric testing as the thermal stimulation may get affected reaching canals in the presence of different cofounding variables such as the thickness of temporal bone, skull size, etc. Moreover, being simple and intuitive, the HIMPs can be easily applied even in young children [53]. In

Complimentary Contributor Copy

addition, HIMPs are found to be useful in examining patients amid acute attacks of vertigo and help discriminate whether the pathology is peripheral and its variants or central in nature [54-57].

Over the years, HIMPs have exposed the possibilities to have reduced VOR gain in single or both canals of the pair [58]. These results have enlightened more on the functioning of the semicircular canals and help explain certain possibilities for having vestibular symptoms with symmetrical normal caloric test results [59]. Moreover, HIMPs have been predominantly utilized for assessing the canal functioning in patients undergoing ototoxic medications such as gentamicin [3, 60], that selectively damage the type I vestibular receptors, vital for the initiation of head impulse responses [61]. Additionally, HIMPs are found to have true sensitivity and specificity of 1.0 as studied in a group of individuals with surgically sectioned vestibular nerve. However, examining the sensitivity and specificity of the test against caloric measure is merely going to provide us with the information on the difference in site of stimulation between the tests, resulting in variable response [62].

Suppression Head Impulse Test Protocols (SHIMPs)

SHIMPs is the recent modification of the HIMPs that utilizes the same vHIT technology while measuring eye and head velocity for the given head impulse. One key variation in SHIMPs is that the participant needs to fixate a head-fixed target wherein the target of laser spot moves along with the head [63]. Therefore, SHIMPs is relatively easier and intuitive as compared to HIMPs as the participant needs to track the moving target for every passive unpredictable head thrust. However, the test results are exactly inverse to that of the standard HIMPs wherein the patients with vestibular loss have no saccades and the healthy participants have large saccadic response at the end of the thrust, also known as anti-compensatory saccade [62]. The comparison of SHIMPs with search coils suggests it to be the valid indicator of vestibular dysfunction and complementary to the HIMPs

Complimentary Contributor Copy

paradigm [63]. The SHIMPs measure two parameters of vestibular function i.e., VOR gain, and saccadic velocity which are useful clinical indicators.

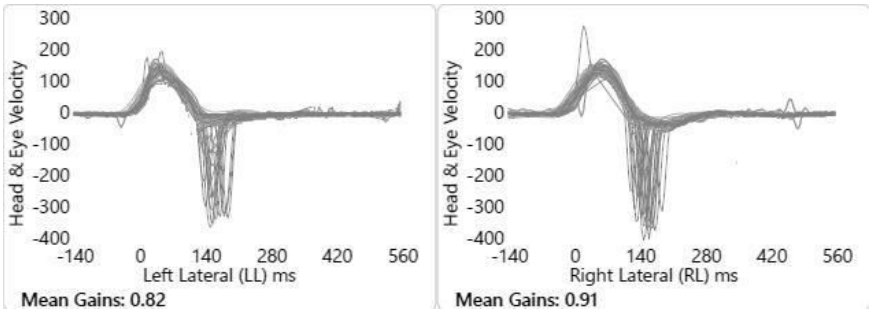

Figure 2. Shows VOR gain and anticompensatory saccade in lateral plane.

For every brief abrupt head impulse, both the HIMPs and SHIMPs stimulate semicircular canal and thereby, compensatory eye movements. HIMPs paradigm stresses on maintaining gaze on the fixed target. However, VOR drives eyes off the target in SHIMPs paradigm. Therefore, the suppression of VOR is seen in healthy participants at around 80 ms from the onset of the head impulse [64]. These compensatory saccades are found to be absent in an individual with complete vestibular loss as they lack VOR to drive the eyes off the target. This suggests the size of the saccade (saccadic velocity) generated by SHIMPs paradigm to be comparable with the VOR gain [65]. For instance, when the head is turned right with active VOR, the gaze is maintained in space by the rotation of eyes to the left. Therefore, as the target is to the right by the end of head impulse, a healthy participant needs to make a large corrective saccade towards the right to maintain gaze at the target. In case of the patient with complete vestibular dysfunction, lack of VOR results in generation of no such corrective saccade. Furthermore, in patients with unilateral vestibular loss, large anti-compensatory saccades are observed for head thrust towards the healthy side and absent or minor one in the affected side [66]. Hence, with its intuitive task, SHIMPs can be well utilized in bedside evaluation where a large anti-compensatory saccade suggests normal functioning of semicircular canals. However, as the compensatory saccades can be affected by the peak head velocity and the

Complimentary Contributor Copy

degree of overshoot at the termination of head thrust, one must be careful during the administration and interpretation of SHIMPs [65].

Precautions Required While Recording Video Head Impulse Test

vHIT is an objective vestibular assessment tool, operated manually by skilled clinicians. However, there should be an understanding of its basics and therefore, cautiousness regarding the possible factors which may alter its diagnostic accuracy such as:

Head Impulse Velocity

Rotation-based tests of vestibular system have their own drawbacks. The head turn in one side results in complementary stimulation of semicircular canals on both sides. In addition, the physiological reports suggest that the neural input from both canals of the same plane responds at the low head velocities [44, 45]. This is more evident in individuals with unilateral vestibular loss wherein with high velocity acceleration of around 150˚/s, the contribution of healthy ear drastically reduces [66].

Stimulus Axis versus Sensor Axis

The vHIT consists of three-dimensional inertial sensor (IMU) and light-weighted goggles. During the assessment, these goggles need to be installed appropriately to the skull as the stimulation applied at the head gets transduced through them. In addition, the stimulation plane should match with the right sensing plane of these goggles, i.e., if the goggles are installed inappropriately, the head velocity sensor axis does not match with the stimulus axis of the head impulse and thus, results in artificial variations in

Complimentary Contributor Copy

VOR gain. Therefore, both the stimulus and sensor axes should be aligned precisely enough for acute measurement of VOR reflex [67, 68].

Geometrical Concerns

During the vHIT assessment, though head turn is the main stimulus, the axis of head rotation rarely lies around the eye being evaluated. Therefore, along with the head turn response, there is a presence of varying within-space translation of the eye along with the gain-changing effect of target distance. The geometrical differences present between the participants with a head carried forward and a stiff neck or those with an upright flexible neck are usually considerable as these effects bring small variations in the test result. However, one should keep these in mind to optimize the results with adjustment in the test setting [66].

Analysis Parameters of Video Head Impulse Test

Based on the Hex plot, the vHIT response can be analysed across three different parameters such as:

- VOR gain
- VOR gain asymmetry
- Refixation saccades

VOR Gain

VOR gain is the most important parameter of the vHIT test and is nothing but the proportion of eye velocity to head velocity from the initiation till its termination of the head impulse. It is measured across three planes of semicircular canals and is ideally considered one. It is calculated by dividing the area curve of eye velocity with no any saccades over the area curve of

Complimentary Contributor Copy

head velocity. Both head and eye velocity curves range from 60ms prior to the peak head and eye acceleration till the head velocity reaches 0°/s back to rest [5, 7]. Therefore, the result is considered normal, if the estimated gain is within the mean and ±2 standard deviation from that of 95% of the population along with no corrective saccades observed [69]. Generally, the VOR gain of ≥ 0.8 is considered normal [50] and clinically utilized across various peripheral vestibular disorders [5, 7, 56, 57, 63] and has reported reduced VOR gain. These are suggestive of the fact that irrespective of the site of lesion (whether the pathology is restricted in the inner ear or vestibular nerve), there is an abnormal reduced gain.

VOR Gain Asymmetry

VOR gain asymmetry is the amplitude-based parameter, calculated by dividing the difference between the VOR gains across orthogonal planes and thus, multiplied by 100. It checks for any intrasensory conflict across RALP, LARLP, and lateral planes of semicircular canals [70, 71]. This sensory unevenness sends variable neural inputs from respective orthogonal planes to the cortical balance system. Such dilemmatic circumstances could generate difficulty in appropriate postural alignment of the body even while the entire head is stimulated with similar acceleration [72, 73]. The asymmetry ratio is well-defined parameter suggesting abnormal vestibular response in cVEMP and oVEMP tests [74]. However, the VOR gain asymmetry is less mentioned across vHIT studies except for a few [71, 75, 76], indicating the need for examining its sensitivity across various clinical conditions.

Refixation Saccades

Refixation saccades, also known as compensatory or corrective saccades, occur when there is variation of the coplanar canals between the stimulated and nonsimulated sides, thereby generating compensatory eye

Complimentary Contributor Copy

movement to sustain the gaze at the target even during the head impulse [21]. With its higher peak eye velocity, these saccades can be distinguished from physiologically induced saccades. Generally, the refixation saccades are of very high velocity which may degrade the retinal image, thereby suppressing the image with its onset until the period of occurrence [77]. These suppressions support in elimination of those smeared retinal images caused due to inadequate slow-phase eye velocity and are mostly seen in vestibular pathologies [44].

Refixation saccades can be classified as the covert and overt as per its time of occurrence. Covert saccades are those that arise prior to the end of the head impulse with a peak eye velocity of 2498/s ± 51 and an average latency of 146 ms ± 28. However, overt saccades occur after the termination of head impulse with peak eye velocity of 1488/s ± 81 and an average latency of 245 ms ± 48. With its late onset, overt saccades are presumed to have central visual trigger mechanism. In contrast, the programming mechanism for covert saccades is still unclear [69]. Yet, the refixation saccades are considered a good indicator of impaired semicircular canals, suggestive of inability to maintain the gaze for the given head impulse [5, 69].

CLINICAL APPLICATIONS OF VIDEO HEAD IMPULSE TEST

Benign Paroxysmal Positional Vertigo

Benign paroxysmal positional vertigo (BPPV) is an inner ear disorder that results from the migration of otoconia into the semicircular canals (canalolithiasis) or their adherence to the cupula (cupulolithiasis). Video head impulse test should show no abnormality in the VOR gain in individuals with BPPV as this disease is a mechanical in nature [78].

Various studies have reported equivocal findings in video head impulse test in individuals with different canals BPPV. In the anterior canal BPPV, gain of the VOR is found within the normal limits for all the semicircular canals both in the affected side and in the contrary. In addition, the mean VOR gain is not significantly different between similar semicircular canals

Complimentary Contributor Copy

in both the ears in individuals with anterior canal BPPV [79]. Moreover, the asymmetry ratio of the VOR gain in individuals with anterior canal BPPV is not significantly different from that of anterior canal BPPV and normal individuals [79]. In posterior canal BPPV, however, the VOR gain is reduced gain in 55.17% of patients in the posterior canal in video head impulse test evaluation [80]. However, in the posterior canal BPPV, the VOR gain of the other semicircular canals are normal. In addition, there is an absence of any corrective saccade (i.e., both covert and overt) in these individuals. Free-floating particles in the posterior semicircular canal that disturb endolymphatic flow lead to VOR and gaze stabilization deficiency [80]. There are other studies that report no differences in the VOR gain between normal individuals and individuals with posterior canal BPPV before and after the canal repositioning maneuver [81]. Similarly, Castellucci et al. reported the reduced VOR gain in individuals with posterior canal BPPV and thereby, hypothesized that the debris alters the endolymphatic dynamics in individuals with BPPV and cupular mechanics results in high-frequency VOR deficit for the involved canal [82]. This condition occurs whenever the otoconial mass is present in the distal portion of the non-ampullary arm of the posterior canal.

Vestibular Neuritis

Vestibular neuritis is characterized by an acute unilateral vestibular loss with sudden vertigo, nausea, and vomiting [83, 84]. Several studies have utilized the video head impulse test in evaluating the deficits of the vestibular nerve in individuals with vestibular neuritis. Bartolomeo et al. reported that the specificity of the video head impulse test in patients with vestibular neuritis is 100% from that of 0 to 40% vestibular deficits shown by the caloric test. Also, the caloric deficit higher than 62.5% is always associated with abnormal VEMP [9]. Moreover, Bartolomeo et al. suggested to avoid the use of caloric test if video head impulse test shows abnormal findings in patients with vestibular neuritis [9].

Complimentary Contributor Copy

The video head impulse test detects an apparent deficit of the lateral semicircular canal in cases with vestibular neuritis. The caloric test also shows a lateral canal deficit in the same set of patients for whom there is evidence of pathology in the lateral semicircular canal [85]. In addition, video head impulse test findings in vestibular neuritis suggest that there could be isolated pathology of the superior vestibular nerve confined only to the nerve supplied to the lateral semicircular canal. Although the anterior and the lateral canals are innervated by the same superior vestibular nerve, video head impulse test results show the pathology confined only to the branch of the superior vestibular nerve supplied to the lateral canals [86].

VOR gain has been used as an essential parameter to characterize the VOR deficits in individuals with vestibular neuritis. The results from the previous study show reduction in VOR gain in individuals with vestibular neuritis [9, 85, 86]. The decrease in VOR gain could be due to the inability of the damaged vestibular nerve in generating the action potential. However, the VOR gain in individuals with vestibular neuritis also depends upon the hand placement technique during the video head impulse test. The mean horizontal VOR gain is lesser for jaw hand placement during the vHIT compared to the head hand position. The jaw hand position can increase the accuracy of vHIT in determining the lesion side [87].

It has been reported that the VOR gain is an excellent parameter to evaluate the VOR deficit at an early stage of vestibular neuritis; however, the sensitivity reduces during follow up evaluation [9, 88, 89]. The sensitivity of the VOR gain in identifying vestibular deficits in patients with vestibular neuritis reduces to 48% compared to the caloric test, which identifies vestibular deficits in 69% of the vestibular neuritis patients at the follow-up evaluation [9]. Similar findings have also been reported in vestibular neuritis patients using the traditional head impulse test wherein the sensitivity of head impulse test has been reported to be 94.4% within one week of symptom, which decreases to 46.2% at 1 year after the onset of symptoms [88]. In another study, Yang et al. also reported that in the acute stage of vestibular neuritis, the abnormal rate of vHIT gain values is 87%, which reduces to 62% at the 1-month follow-up [90]. It has been suggested

Complimentary Contributor Copy

that the central compensation might be responsible for the recovery of VOR gain in vestibular neuritis patients [90].

Meniere's Disease

The patients with Ménière's disease (MD) always present with clinical features of cochleovestibular dysfunction such as hearing loss, tinnitus, and vertigo [91, 92]. The abnormality rate of video head impulse test (vHIT) in patients with Meniere's disease is about 25%, and the sensitivity of the vHIT along with a caloric test in identifying vestibular pathology in Meniere's disease is about 55% [35]. The VOR gain abnormality has been reported in many patients with Meniere's disease [35, 93]. In addition, the vertigo attack is often associated with a quick change in VOR gain on the side of the affected ear. There is a reduction of VOR gain in the paralytic nystagmus phase and the VOR gain becomes normal in the recovery phase [93]. Manzari et al. also reported that VOR gain is enhanced before the Meniere's attack, then decreases during the Meniere's attack but remain above the normal limit [54]. Few studies suggest normal VOR gain in patients with Meniere's disease [32, 94]. Other studies suggest VOR gain to be abnormal in 45-73% of the patients with Meniere's disease [69, 95, 96]. The discrepancies in various results can be attributed to the differences in severity, with abnormal vHIT test results emerging later in the disease course than abnormal caloric reflex.

Discrepancy has also been absorbed between the test results of caloric and vHIT [32, 69, 97] and can be explained by the neurophysiology of the crista [97]. In the peripheral vestibular system, there are two types of nerve fibers, irregular nerve fibers, and regular nerve fibres. These regular nerve fibers are responsible for selective processing of the caloric test stimulus and the vHIT test stimulus [97]. The neurons with regular firings are innervated to type II hair cells in crista ampullaris, whereas the neurons with irregular firings are innervated to type I hair cells of the crista ampularis. It is possible that there can be selective damage to the Type I or type II hair cells in individuals with Meniere's disease such that the disagreement can appear

Complimentary Contributor Copy

between the caloric and vHIT test findings [97]. Similar discrepancy has also been reported in individuals with delayed endolymphatic hydrops [98].

Auditory Neuropathy Spectrum Disorders

Auditory Neuropathy spectrum disorders (ANSD) are characterized by the presence of otoacoustic emissions/cochlear microphonics along with absent or abnormal auditory brainstem responses. Most of the studies in the literature have described the auditory deficits in individuals with ANSD; however, a significant proportion of the individuals also have deficits of the vestibular system [38, 83, 99-101]. In the literature, there are only a few studies that have reported video head impulse test findings in ANSD. The results of the studies show that the VOR gain is reduced for all the six semicircular canals in almost all the individuals with ANSD [15]. In addition, the presence of both covert and overt saccades are often reported in these individuals with ANSD. However, no correlation has been observed between the duration of the condition and the VOR gain values as well as pure tone thresholds and the VOR gain values. Moreover, no association has been revealed between the VOR gain values and the presence or absence of saccades in any of the semicircular canals in these individuals [15]. Sinha et al. also reported no association between caloric test and the video head impulse test in individuals with ANSD [102]. It was reported to have hypofunctional caloric responses along with reduced vestibulo-ocular reflex (VOR) gain and presence of refixation saccades in two individuals with ANSD (ANSD). However, one of the ANSD participant also had hypofunctional caloric response along with normal VOR gain and absent refixation saccade. Hu et al. also reported abnormal caloric test in 70% of the individuals with ANSD [103]. However, most of the ANSD participants showed normal VOR gains with no overt corrective saccades, and exhibited normal anti-compensatory saccades in the SHIMPs paradigm. Thus, the findings of the video head impulse test along with other test indicate a vestibular pathology in individuals with ANSD and the vestibular evaluation for all the individuals with ANSD must be done along with the auditory tests.

Vestibular Schwannomas

Vestibular schwannomas (VS) are benign tumors that originate from the Schwann cells of the vestibulocochlear nerve. Various studies have calculated the sensitivity of the vHIT test in detecting the VOR pathology in individuals with vestibular schwannoma. These studies have reported a sensitivity of 36% to 80% in detecting the VOR deficit in individuals with vestibular schwannoma [19, 40, 76, 104, 105]. The VOR gain is one of the most important parameters that has been evaluated in individuals with vestibular schwannoma. The VOR gain is found to be reduced in 35-59% of the subjects on the tumor side [76, 106]. The reduction in VOR gain in these individuals can also depend upon the tumor size. VOR gain deficits range from 13.0–34.8% for schwannoma less than 15 mm to over 70.0% for schwannoma exceeding a 29 mm diameter [106]. As the video head impulse test, along with other vestibular tests, suggests a significant relationship between tumor size and the vestibular test results, which implies a potentials role of these tests as a monitoring tool when MRI is not accessible [106].

The asymmetry ratio is abnormal in 50-68% of the subjects diagnosed with vestibular schwannoma [75, 76]. The asymmetry ratio could be higher in individuals with vestibular schwannoma because of the VOR gain deficit on the tumor side. Saccades are present in almost all the patients with vestibular schwannoma and are indicated as a much better parameter than VOR gain for detecting VOR deficit in vestibular schwannoma [75, 76, 106]. Blödow et al. found saccades associated with VS in 19 patients, of which 11 exhibited both covert and overt saccades, seven isolated overt and one isolated covert [69]. However, there are other studies to show that the distribution of saccades is even between isolated overt saccades and the combination of overt and covert saccades [76]. Also, there is a significant relationship between the asymmetry ratio of the VHIT gain and the occurrence of saccades. The presence of saccades is more prevalent in individuals with more gain asymmetry [76]. Also, the occurrences of saccades are associated with more severe canal paresis in individuals with vestibular schwannoma.

Complimentary Contributor Copy

There are some reports on the dissociation between caloric and vHIT test results in identifying the VOR gain deficits [76, 107]. Such dissociations between the caloric test and vHIT test could result from the size of the tumor, site of the tumor, and extent to which the tumor is compressing the different vestibular nerve fibers [76, 107]. It is postulated that the copular neuroepithelium reacting for rapid stimuli in vHIT test could have a different sensitivity for the tumor compression compared to that arising from the slow reacting neuroepithelium responsible for the neuronal firing responsible for caloric test [76]. However, the caloric test is superior to vHIT in detecting the abnormal function of horizontal canal VOR [69]. The caloric test reflects low-frequency VOR changes, and vHIT reflects high-frequency VOR changes. The combination of both the test reveals the abnormal function of both the high frequency and well as low-frequency VOR deficit. It has been recommended that vHIT should be administered along with a caloric test in individuals with vestibular schwannoma [69].

Central Disease Mimicking Peripheral Vertigo

There are patients with isolated cerebellar infarction who have clinical features suggesting vestibular neuritis. The frequency of such patients visiting emergency medical services is about 10% [108, 109]. Two types of cerebellar infarction have clinical features identical to vestibular neuritis: isolated prolonged spontaneous vertigo with imbalance as a sole manifestation of cerebellar infarction and isolated prolonged spontaneous vertigo with imbalance as an initial manifestation of cerebellar infarction followed by delayed neurologic deficits two days after the onset [108]. Mantokoudis et al. reported that the vHIT sensitivity is superior to MRI in the first 48 hours to differentiate peripheral lesions (VOR presents a lowered gain) from central lesions, where VOR gain is normal [47]. Also, VOR gain and compensatory saccades differ between pontine cerebellar stroke and vestibular neuritis. In individuals with vestibular neuritis, VOR gain is reduced along with large amplitude saccades whereas, the VOR gain in AICA stroke is reduced bilaterally with small amplitude stroke. In PICA

Complimentary Contributor Copy

stroke, there is a contralesional gain bias with the smallest saccades, saccades smaller than vestibular neuritis, and AICA stroke [110].

Older Adults

In older adults, VOR gain has been reported to be significantly reduced across all the six semicircular canals [111-113]. The VOR gain declines every decade as the age increases [49]. The decline in the number of receptor cells and the primary afferents of vestibular system could be the reason for reduction in VOR, gain values with age. In healthy young adults, there are a very considerable number of receptors in each canal, and this number declines with age [20, 40, 114-116].

Li et al. suggested the relationship between VOR gain and age to be non-linear [117]. As the age increases, there is a considerable reduction in VOR gain especially in older adults above 80 years of age. Matiño-Soler et al. reported significant reduced VOR gain in individuals above 70 years of age [118]. Kim & Kim reported significant reduction in VOR gain of the horizontal canal above 70 years and in the vertical canal above 80 years of age [119]. Jay et al. reported a significant decline in VOR gain in the age groups 58–67 and 68–77 years [120]. Agrawal et al. also reported not much change seen in the VOR gain up to the age of 50 years; however, the mean VOR gain is reduced in individuals beyond 60 years [113]. In contrary, few studies have also reported no change in vestibulo-ocular reflex gain reduction for the increment in age. MacDougall et al. reported that vHIT have not referenced the variation of normal horizontal VOR velocity gain concerning age [3]. McGarvie et al. found that the horizontal canal gain and anterior canal gain did not vary largely with age except the average gain for the posterior canal [31]. Shizhen also reported that the gain of vHIT six semicircular canals, VOR has excellent age stability, and the age difference will not affect the vHIT result [121].

The cerebellum controls the oculomotor response measured, and studies on the VOR has shown how essential is the cerebellum is for “restoring” the VOR in the face of “challenges,” such as magnified vision or may be age

Complimentary Contributor Copy

[114]. The cerebellar repair may be the reason for such relatively inconsequential effect of age. The reduction in VOR gain could start at the age of 40 Years [122]. The reduction in VOR gain is consistent with the histopathologic reports presenting remarkable age-related deterioration in the number of vestibular sensory hair cells in human temporal bones [123-125] and also with the loss of neurons in the human vestibular nucleus complex after the age of 40 years [126].

PUBLISHER NOTE

Online Gatha is a step into the online literary world. It works by connecting the hardcopy creations to the online world.

This book has been published in the good faith that the work of the author is original. All efforts have been taken to make the book error free.

The author maintains the copyright of the book and no parts of this book can be reproduced in any manner without the written permission from publisher and the author.

ACKNOWLEGEMENT

I take this opportunity to convey my respect, gratitude and heartfelt thanks to all people who have helped me throughout the process of writing this Book.

I have always believed that without the support of your family you cannot accomplish your goal so, first and foremost I would like to thank my parents **Vilas Gavali and Hemlata Gavali,** my brother, **Sameer Gavali,** my husband**, Rajeshkumar Kakde** and my children **Ridhima Kakde and Rehansh Kakde** for their continous help, encouragement, affection and moral support all throughout without which this would have not been possible. I would also like to thank god for giving this opportunity and helping me to complete my work successfully.

To begin with, I wish to express my gratitude towards my Post graduate Guide, **Dr Vishakha Patil**, Professor, Department of Periodontology, for her unparalleled guidance and enthusiastic supervision throughout writing this book. She is and always be my role model for all my academic endeavours, her motherly approach and suggestions always increased my inspiration and guided me to do my work with maximum devotion.

I am indebted to **Dr. Amita Mali** for her continuous support and encouragement.

I would also like to extend my profound respect towards **Dr. Rohini Mali** for her guidance and suggestions.

Special thanks to **Dr. Pramod Waghmare,** Professor, Department of Periodontology who continuously supported and guided my work throughout. He encouraged my every practical work and publications, his suggestions always increased my inspiration and guided me to do my work with maximum sincerity and devotion.

I would also like to express my sincere gratitude and thanks to**, Dr Amit Chaudhari and Dr. Nilima Landge** for their invaluable advice, guidance, encouragement and support. I thank Dr. Priya Lele, Dr. Priyanka Agarwal, Dr. Yogesh Khadtare and Dr. Prakash Vhatkar, Dr Pallavi Patil, Dr Shilpa Chaudhary for their support.

It would be unfair on my part if I do not thank my colleagues and friends especially Dr Ketki, Dr Divyanshu, Dr Nishita, Dr Pooja K, Dr Rinkoo, gratefully acknowledge the generous support by non-teaching staff.

DR NEELAM GAVALI/KAKDE

CHAPTER: 1

INTRODUCTION

Periodontitis is common chronic infections of the adult population characterized by an exaggerated gingival inflammatory response against a pathogenic bacterial microflora, resulting in clinical attachment loss, alveolar bone loss, and eventually tooth loss.

The primary etiological agent in periodontal disease is bacterial plaque.

The toxins and the enzymes produced by the bacterial plaque elicit inflammatory and immunologic changes in the periodontal tissues at both cellular and molecular levels.

Periodontal pathogen, Porphyromonas gingivalis which release lipopolysaccharide, increases Tumour necrosis factor-α which induces the insulin resistance and atheromatous changes.

Periodontitis is also associated with systemic alterations like low-grade inflammation, dyslipidemia, glucose intolerance, endothelial dysfunction.

The term metabolic syndrome (MetS) which was first coined by Haller and Hanefeld in 1975 , is characterized as a combination of underlying risk factors that when occurring together, culminate in adverse outcomes, including type 2 diabetes mellitus (T2DM), cardiovascular disease (CVD) and thus an approximately 1.6-fold increase in mortality.

The metabolic syndrome is a constellation of metabolic derangements such as insulin resistance, hyperinsulinemia, abdominal obesity, impaired glucose tolerance, dyslipidemia, hypertension, and a proinflammatory and prothrombotic state (Reaven GM, 1988).

The major risk factors for developing MetS are physical inactivity and a diet high in fats and carbohydrates.These are often related to the individual's life style (overweight, sedentary habits), or existing pathological conditions (e.g. obesity and hypercholesterolemia)(Lakka et al. 2002)

The hyperinsulinemia-artherosclerotic cardiopathy association is high in rate also after a correction of triglycerides, apolipoprotein B, LDL cholesterol, and HDL cholesterol levels.

Therefore, high insulin plasmatic concentrations in non-diabetic individuals who can be classified as 'insulin-resistant' – were associated with an ischemic cardiopathy increase, independently from the lipid profile (although a lipid profile alteration in proatherogen sense has a synergic effect with hyperinsulinemia) (Després et al. 2000).

In metabolic syndrome there is an elevation in circulating proinflammatory cytokines and a procoagulant state exists with elevation of C-reactive protein and fibrinogen.

Both periodontitis and metabolic syndrome are associated with systemic inflammation and insulin resistance with elevation in WBC count as a result of body's defence mechanism.

Considering chronic inflammation as the basis for the association between periodontal disease and metabolic syndrome they can be linked through a common patho physiological pathway.

Periodontal disease and metabolic syndrome has bidirectional association (Y. Shimazaki 2007)

Not only systemic diseases have impact on oral health but oral diseases like periodontal diseases have wide ranging systemic effects.

In susceptible individuals, periodontal infection acts as an independent risk factor for systemic diseases and may be involved in the basic mechanism of these conditions.

The pathogenic bacteria alone is not sufficient to create an disease rather the disease initiation and progression also depends on host susceptibility.

In a person affected by MetS, a hyperglycaemia status triggers cellular damage with repercussions at the systemic level and also on periodontal tissue. Periodontal diseases of diabetic origin are a clear example of this (Bensley et al. 2011).

New studies focus on the aetiology of periodontal diseases and the role of oxidative stress, starting a cascade of molecular signals from inflammation mediators, which cause loss of attachment, reabsorption of alveolar bone, and, ultimately, tooth loss, through activation of osteoclasts (Pietropaoli et al. 2010).

As a source of oxidative stress, the MetS could provide an alternative etiological explanation to the development of periodontal disease, as suggested by Bullon et al. (2009).

Periodontitis is a chronic inflammatory disease caused by periodontal pathogens in presenceof local factors which is significantly associated with the frequency of tooth brushing, regular dental visits, smoking and drinking habits (Y. Shimazaki, 2007).

The consequence of chronic periodontal infection is the synthesis of inflammatory cytokines and chemokines by local periodontal tissue or circulating inflammatory cells.

The inflammatory cytokines such as interleukin-6, Tumour necrosis factor-α, elevated C-reactive protein level evokes systemic inflammation which contributes to insulin resistance and causes hyperglycemia,which in turn induces the expression of proinflammatory mediators and increases the risk of oral infection and cardiovascular disease among patients with periodontitis Chen LP,Chaing CK,Chan CP et al(2006).

Thus a triangular vicious circle among periodontitis, systemic inflammation and hyperglycemia is perpetuated. (Kirk EP, Klien S 2009).

CHAPTER:2

DEFINITIONS OF METABOLIC SYNDROME

A number of expert groups have attempted to develop a unifying definition for the MetS.

The most widely accepted of these definitions have been produced by the World Health Organization (WHO), The European Group for the Study of Insulin Resistance (EGIR) and the National Cholesterol Education Program—Third Adult Treatment Panel (NCEP ATP III).

All groups agreed on the core components of the MetS: obesity, insulin resistance, dyslipidaemia and hypertension.

WHO (1999) [1] suggested a working definition of metabolic syndrome (MS), which was to be improved in due course of time. WHO defined MS as glucose intolerence, impaired glucose tolerance (IGT) or diabetes mellitus (DM), and/or insulin resistance, together with two or more of the components listed below:

1. Raised arterial pressure, i.e., ≥140/90 mm of Hg

2. Raised plasma triglyceride (≥ 150 mg/dl) and/or low HDL-C (<35 mg/dl in men and <39 mg/dl in women)

3. Central obesity, i.e., waist/hip ratio (WHR) >0.9 in men and >0.85 in women and/or body mass index (BMI) >30 kg/m^2

4. Microalbuminuria, i.e., urinary albumin excretion rate ≥ 20 μgm/minute or albumin/creatine ratio ≥ 30μgm/mg.

The European Group for Study of Insulin Resistance (EGIR) (1999)[2] proposed a modification of the WHO

definition, using the term insulin resistance syndrome rather than MS.

According to the EIGR definition the diagnostic criteria included elevated plasma insulin (>75th percentile) plus two other factors from among the following:

1. Abdominal obesity: waist circumference (WC) ≥94 cm in men and ≥80 cm in women

2. Hypertension: ≥140/90 mm of Hg or on antihypertensive treatment

3. Elevated triglycerides (≥150 mg/dl) and/or reduced HDL-C (<39 mg/dl for both men and women)

4. Elevated plasma glucose: impaired fasting glucose (IFG) or IGT, but no diabetes.

EGIR focused more on abdominal obesity than did WHO, but in contrast to WHO, EGIR excluded patients with type 2 DM from their syndrome because insulin resistance was viewed primarily as a risk factor for diabetes.

National Cholesterol Education Program Adult Treatment Panel III (NCEP ATP III) (2001)[3] **:** Defined a subject has the MS if he or she has three or more of the following criteria:

1. Abdominal obesity: WC ≥102 cm in men and ≥88 cm in women

2. Hypertriglyceridemia: ≥150 mg/dl (1.695mmol/l)

3. Low HDL-C: <40 mg/dl in men and <50 mg/dl in women

4. High blood pressure (BP): >130/85 mmHg

5. High fasting glucose: >110 mg/dl

This definition differs from the WHO definition on several fronts.

The NCEP ATP III did not believe that insulin resistance is mandatory for the development of MS and hence suggested the term MS instead of the previously used term ‘insulin

resistance syndrome.' This definition recognizes central obesity as the culprit and hence body mass index (BMI,) which is a parameter for generalized obesity, has not been included in this definition.

The NCEP ATP III definition is much more practically applicable. The NCEP ATP III considers the proinflammatory state and prothrombotic state as components of MS though these have not been included among the criteria necessary to define MS.

The American Association of Clinical Endocrinologists (AACE) (2002) [4] too preferred using the term insulin resistance syndrome over MS. The major criteria they considered were Impaired glucose tolerance (IGT), elevated triglycerides, reduced HDL-C, elevated BP, and obesity. They did not specify any particular number of criteria for diagnosis, rather they left it to clinical judgment.

They suggested that factors like family history of atherosclerotic cardiovascular disease or type 2 DM, polycystic ovary syndrome, and hyperuricemia be considered while exercising clinical judgement.

Patients with type 2 DM were excluded from the definition of insulin resistance syndrome. The various components suggested by the AACE are as follows:

1. *Some degree of glucose intolerance:*

• IFG/IGT

2. *Abnormal uric acid metabolism:*

• Plasma uric acid concentration

• Renal uric acid clearance

3. *Dyslipidemia:*

• Triglycerides

• HDL-C

• LDL particle diameter (small, dense LDL-particles)

• Postprandial accumulation of TG-rich lipoproteins

4. *Hemodynamic changes:*

• Sympathetic nervous system activity

• Renal sodium retention

• Blood pressure (~50% of patients with hypertension are insulin resistant)

5. *Prothrombotic factors:*

• Plasminogen activator inhibitor-1

• Fibrinogen

6. *Markers of inflammation*

• C-reactive protein, white blood cell count, etc.

7. *Endothelial dysfunction:*

• Mononuclear cell adhesion

• Plasma concentration of cellular adhesion molecules

• Plasma concentration of asymmetric dimethyl arginine

• Endothelial-dependent vasodilatation

ADA lowered the fasting plasma glucose threshold used to identify individuals with IFG from 110 mg/dl to 100 mg/dl. Subsequently, the NCEP ATP III has also suggested that the fasting plasma glucose concentration for diagnosing MS be lowered to 100 mg/dl.

Researchers worldwide preferred using the NCEP ATP III definition because it was relatively simple and clinically applicable.

The International Diabetes Federation (IDF) (2005)[5] released a global consensus definition for Metabolic Syndrome, along with race and gender-specific WC cutoffs.

This definition identified central obesity as an essential component of MS and defined MS as central obesity (based

on race- and gender-specific WC cutoffs) plus any two of the following four parameters:

- Raised triglycerides: ≥150 mg/dl (1.7 mmol/l) or history of specific treatment for this lipid abnormality.
- Reduced HDL cholesterol: < 40 mg/dl (1.03 mmol/l) in males and < 50 mg/dl (1.29 mmol/l) in females or history of specific treatment for this lipid abnormality.
- Raised blood pressure: systolic BP ≥130 mm Hg or diastolic BP ≥85 mm Hg or on treatment for previously diagnosed hypertension.
- Raised FPG: ≥ 100 mg/dl or previously diagnosed type 2 DM

The race- and gender-specific WC cutoffs suggested are:

Country/Ethnic group	Waist circumference cutoff	
	Male	Female
Europids In the USA, the ATP III values (102 cm male; 88 cm female) are likely to continue to be used for clinical purposes	≥94 cm	≥80 cm
South Asians Based on a Chinese, Malay, and Asian-Indian population	≥90 cm	≥80 cm
Chinese	≥90 cm	≥80 cm
Japanese	≥90 cm	≥80 cm
Ethnic South and Central Americans	Use South Asian recommendations until more	

	specific data are available
Sub-Saharan Africans	Use European data until more specific data are available
Eastern Mediterranean and Middle East (Arab) populations	Use European data until more specific data are available

CHAPTER:3

PATHOPHYSIOLOGY OF METABOLIC SYNDROME

1: Insulin Resistance and Glucose Intolerance:

Metabolic Syndrome is also popularly known as Insulin resistance syndrome. This syndrome is a group of disorders like insulin resistance, impaired glucose intolerance. Insulin resistance is the primary mediator of metabolic syndrome (Lann D, LeRoith D (2007).

It is defined as a pathophysiological condition in which a normal insulin concentration does not adequately produce a normal insulin response in the peripheral target tissues such as adipose, muscle, and liver.

Insulin is a pleiotropic molecule that affects the amino acid uptake, protein synthesis, proteolysis, adipose tissue triglyceride lipolysis, lipoprotein lipase activity, very low density lipoprotein (VLDL) triglyceride secretion, muscle and adipose tissue glucose uptake, liver glycogen synthesis, and endogenous glucose production[7].

Physiological insulin signalling occurs following the binding of insulin to the insulin receptor, a ligand-activated tyrosine kinase.

Insulin promotes glucose uptake in muscle, fat, and liver cells and can influence lipolysis and the production of glucose by hepatocytes. Insulin is an antiatherogenic hormone and this metabolic effect involves the activation of phosphatidylinositol (PI) 3-kinase.

Binding of insulin results in a tyrosine phosphorylation of downstream substrates and activation of two parallel pathways:

1: The phosphatidylinositol phoinositide 3-kinase (PI3K) pathway.

2: The mitogen activated protein (MAP) kinase pathway.

The PI3K pathway is affected, while, the MAP kinase pathway functions normally in insulin resistance. This leads to a change in the balance between these two parallel pathways.

Inhibition of the PI3K pathway leads to a reduction in endothelial NO production, resulting in an endothelial dysfunction, and a reduction in GLUT4 translocation, leading to a decreased skeletal muscle and fat glucose uptake.

By contrast, the MAP kinase pathway is unaffected, so there is a continued endothelin-1 (ET-1) production, an expression of vascular cell adhesion molecules, and a mitogenic stimulus to vascular smooth muscle cells.

Although hyperinsulinemia may compensate for insulin resistance to some biological actions of insulin, that is, maintenance of normoglycemia, however, it may cause an overexpression of insulin activity in some normally sensitive tissues.

In these ways, an insulin resistance leads to the vascular abnormalities that predispose to atherosclerosis. Although insulin-resistant individuals need not be clinically obese, they commonly have an abnormal fat distribution that is characterized by a predominant upper body fat.

Characteristics of the insulin-sensitive phenotype include a normal body weight, without abdominal or visceral obesity, being moderately active, and consuming a diet low in saturated fats. Under this condition, pancreatic beta cell secretes more insulin (i.e., hyperinsulinemia) to overcome the hyperglycemia among insulin-resistant individuals.

This accentuation of some insulin actions coupled with a resistance to other actions of insulin results in the clinical manifestations of MetS.

An inability of the pancreatic beta cells over time to produce a sufficient insulin to correct the worsening tissue insulin resistance leads to hyperglycemia and overt T2DM.

Regardless of the relative contributions of visceral fat and abdominal subcutaneous fat to insulin resistance, a pattern of abdominal (or upper body) obesity correlates more strongly with the insulin resistance and the MetS than does lower body obesity.

In case of insulin resistance, PI 3- kinase path is impaired and insulin is no longer antiatherogenic (Wang et al 2004).

Obesity, mainly abdominal adiposity is one of the main reasons for insulin resistance. Non-esterified fatty acids (NEFA) are released from excess adipose tissues, which increase insulin resistance.

In case of Insulin resistance there is increased lipolysis from the adipose tissue which increases the free fatty acids, further inhibiting the anti-lipolytic effect of Insulin. (Eckel et al 2005).

Visceral or omental fat appears to be the most detrimental and contributes most to the development of lipotoxicity in peripheral tissues by the secretion of adipocytokines. (Gill et al 2005).

Metabolic Syndrome is associated with a high amount of intra-abdominal fat, low adiponectin levels, and elevated levels of cytokines (interleukin 1RA and interleukin 1beta). (Salmenniemi et al 2004).

Hyperinsulinemia can increase the production of very low-density lipoprotein triglycerides and thus raise triglycerides. Insulin resistance can raise blood pressure (Grundy, 2004).

Additional contributors to insulin resistance include abnormalities in insulin secretion and insulin receptor signaling, impaired glucose disposal, and proinflammatory cytokines.

To compensate for defects in insulin activity, insulin secretion or clearance needs to be modified to sustain normal glucose levels.

Hyperglycemia is the end result if these mechanisms fail (Eckel et al 2005). Since insulin resistance increases a person's risk for developing cardiovascular disease and Type 2 diabetes, several researchers have proposed measures of insulin resistance in obese individuals with and without Metabolic Syndrome.

Reilly et al (2004) believed that insulin assays or alternative biomarkers of insulin resistance may facilitate cardiovascular risk prediction in individuals with Metabolic Syndrome.

2: Central Obesity:

According to the new criteria of IDF, Metabolic syndrome can also be called as ―central obesity syndrome‖ (Gary 2006). The importance of the term Metabolic syndrome is that it helps identify people at risk of Cardiovascular disease and Type 2 Diabetes (Ford 2005).

Central obesity is a high cardiovascular disease risk factor.

Central obesity is more metabolically active then peripheral fat.

The "obesity epidemic" is principally driven by an increased consumption of high calorie unhealthy food intake and reduced physical activity.

Adipose tissue is a heterogeneous mix of adipocytes, stromal preadipocytes, immune cells, and endothelium, and it can respond rapidly and dynamically to alterations in nutrient excess through adipocytes hypertrophy and hyperplasia.

With obesity and progressive adipocytes enlargement, the blood supply to adipocytes may be reduced with consequent hypoxia.

Hypoxia has been studied to be an etiology of necrosis and macrophage infiltration into adipose tissue that leads to an

overproduction of biologically active metabolites known as adipocytokines which includes glycerol, free fattyacids (FFA), proinflammatory mediators (tumor necrosis factor alpha (TNFα) and interleukin-6 (IL-6)), plasminogen activator inhibitor-1 (PAI-1), and C-reactive protein (CRP). This results in a localized inflammation in adipose tissue that propagates an overall systemic inflammation associated with the development of obesity related comorbidities.

Adipocytokines combine the endocrine, autocrine, and paracrine signals to mediate the multiple processes including insulin sensitivity, oxidant stress, energy metabolism, blood coagulation, and inflammatory responses which are thought to accelerate atherosclerosis, plaque rupture, and atherothrombosis.

Pladevall, et al. 2006 & Steele et al 2004, recommended that waist circumference should be routinely measured to assess individuals for increased risk for insulin resistance related cardiovascular disease, Metabolic Syndrome and Type 2 diabetes and to target individuals for health promotion interventions.

Though Insulin resistance is known to be the major risk factor for the development of metabolic syndrome but it is suggested that obesity provides the connection between the insulin-resistant, dyslipidemic and hypertensive factors (Wingard et al 1996).

Visceral fat releases their metabolic products directly into portal circulation, which carries blood straight to the liver. Therefore free fatty acids are poured into the liver. Free fatty acids also accumulate in the pancreas, heart and other organs. This leads to organ dysfunction, producing impaired regulation of insulin, blood sugar and cholesterol as well as abnormal heart functions. This is known as lipotoxicity (Havard College 2006). Thus it can be evaluated that abdominal obesity by use of computed tomography (CT) or magnetic resonance imaging (MRI) can measure the amount of visceral fat.

The National Cholesterol Education Programme Adult Treatment Panel III suggested cut off of 102 cm (40 in) and 88 cm (35 in) for males and females as a marker of central obesity. Parikh et al 2006 proposed that Index of central obesity, which is the ratio of waist circumference and height, was a better substitute than the widely used waist circumference. Central obesity is correlated with both insulin resistance and Type 2 Diabetes Millitus (Gabriely et al 2002).

3: Hypertension

One of the key symptoms of metabolic syndrome is hypertension. It is one of the silent symptom which may remain undetected for long.

It is an important risk factor for development of cardiovascular disease. All the hemodynamic and metabolic disorders of essential hypertension and insulin resistance are closely related.

Essential hypertension is frequently associated with several metabolic abnormalities, of which obesity, glucose intolerance, and dyslipidemia are the most common (Ferranini et al 1991).

Obesity may be the strongest risk factor for uncontrolled hypertension. Studies have shown that obesity provides a connection between hypertension, insulin resistance and dyslipidemia. (Wingard et al 1996). Three factors are found in clustering of metabolic variables ie insulin resistance, hypertension and dyslipidemia.

Both general and central obesity was associated with insulin resistance and hypertension and only weakly linked to dyslipidemia (Anderson PJ et al 2001). The results of Farmingham Heart Study estimate the risk of excess weight was the cause of hypertension in 78% of men and 65% of women (Morse et al 2005).

Studies also suggest that both hyperglycemia and insulin activate the RAS (Renin-Angiotensin System) by increasing the expression of angiotensinogen, AII, and the AT1

receptor, which, in turn, may contribute to the development of hypertension in patients with insulin resistance (Malhotra et al 2001).

There is also evidence which supports a strong relation between hypertension and obesity, which may involve insulin and leptin as well as sympathetic nervous system.

4: Dyslipidemia:

Dyslipidemia is characterised by a wide range of qualitative lipid abnormalities reflecting perturbations in the structure, metabolism, and biological activities of both atherogenic lipoproteins and antiatherogenic , high-density lipoprotein(HDL-C) which includes an increase of lipoproteins containing apolipoprotein B (apoB), elevated triglycerides, increased levels of small particles of LDL, and low levels of HDLC.

Insulin resistance leads to an atherogenic dyslipidemia in several ways. First, insulin normally suppresses lipolysis in adipocytes, so an impaired insulin signalling increases lipolysis, resulting in increased free fatty acids levels. In the liver, FFAs serve as a substrate for the synthesis of TGs. FFAs also stabilize the production of apoB, the major lipoprotein of very low density lipoprotein (VLDL) particles, resulting in a more very low density lipoprotein production.

Second, insulin normally degrades apoB through PI3K-dependent pathways, so an insulin resistance directly increases very low density lipoprotein production.

Third, insulin regulates the activity of lipoprotein lipase, the rate-limiting and major mediator of VLDL clearance. Thus, hypertriglyceridemia in insulin resistance is the result of both an increase in VLDL production and a decrease in VLDL clearance.

VLDL is metabolized to remnant lipoproteins and small dense LDL, both of which can promote an atheroma formation. The TGs in VLDL are transferred to HDL by the cholesterol ester transport protein (CETP) in exchange for

cholesterol esters, resulting in the TG-enriched HDL and cholesterol esters rich VLDL particles.

Further, the TG-enriched HDL is a better substrate for hepatic lipase, so it is cleared rapidly from the circulation, leaving a fewer HDL particles to participate in a reverse cholesterol transport from the vasculature.

Thus, in the liver of insulin-resistant patients, FFA flux is high, triglycerides synthesis and storage are increased, and excess TG is secreted as VLDL. For the most part, it is believed that the dyslipidemia associated with insulin resistance is a direct consequence of increased VLDL secretion by the liver. These anomalies are closely associated with an increased oxidative stress and an endothelial dysfunction, thereby reinforcing the proinflammatory nature of macrovascular atherosclerotic disease.

A study by Brown et al (2001) in the Kaiser Permanente Northwest population, reported the correlation between fasting lipids, HbA1c in 11938 persons with diabetes.

The study compared persons with no, one and two high-cardiovascular diseases (CVD) risk lipid abnormalities, the HbA 1c was 7.3, 7.5 and 7.9%, triglycerides 150, 210 and 318 mg/dl and HDL 54, 40 and 37 mg/dl respectively. This suggested a poorer glycemic control with dyslipidemia in type 2 diabetes.

Another study by Lamarche et al (1997), reported that the presence of small, dense LDL particles may be associated with an increase of subsequently developing Ischemic heart disease. LDL particle size shows no correlation with the LDL cholesterol, but it is strongly correlated with triglyceride and HDL cholesterol concentrations and with the cholesterol–to–HDL cholesterol ratio.

In fact elevated triglycerides and low levels of HDL cholesterol characterize dyslipidemia in Metabolic Syndrome.

In the presence of insulin resistance and hyperinsulinemia, the circulating free fatty acids result in the formation of triglycerides. Sniderman et al (2003) in a symposium on approaches to lipid-lowering treatment in persons with diabetes presented the analysis of hypertriglycerides apo B.

It was concluded that the true target in the treatment for diabetes should be apo B rather than LDL cholesterol. Without measurement of apoB molecule, one cannot distinguish with hypertriglyceridemia and large particles whose apoB is normal.

5: ProInflammatory State:

A proinflammatory state is characterized by elevated circulating cytokines and acute-phase reactants (e.g., CRP).

Yudgin et al (1999) noted that low-grade inflammation is associated with insulin resistance and endothelial dysfunction and that adipose tissue generates inflammatory cytokines that may link insulin resistance with vascular disease.

The origin of the inflammatory state and of endothelial dysfunction was adipocyte-generated inflammatory cytokines, which correlate strongly with insulin resistance.

Circulating signal molecules from fat could include Free Fatty Acids, adiponectin, IL-6 (particularly at the liver, where IL-6 increases CRP production), resistin, leptin, and TNF-α.

This study has sought associations of levels of C-reactive protein and interleukin-6 with measures of obesity and of chronic infection as their putative determinants.

The study also related levels of C-reactive protein and interleukin-6 to markers of the insulin resistance syndrome and of endothelial dysfunction.

Metabolic syndrome and obesity are a kind of stress that leads to activation of inflammatory pathways.

The causation of inflammation is multifactorial. The inflammation in metabolic syndrome is not accompanied by

infection, autoimmunity or massive tissue injury. In fact the inflammation is low grade chronic inflammation.

A few studies have confirmed the positive association between obesity indices and inflammatory markers, mainly CRP (C - reactive protein) in women (Shemesh 2007), but also other inflammatory markers, both in women and men (Mortensen 2009).

Increased concentrations of inflammatory mediators, such as, C-reactive protein, tumor necrosis factor-alpha, interleukin-6 and others have been found in the obese.

Adipose tissue has been found to express most of these inflammatory markers. Obesity was the most important feature associated with C-reactive protein. (Dandona et al 2005).

6: Prothrombotic state:

A prothrombotic state signifies anomalies in the procoagulant factors, that is, an increase in fibrinogen, factor VII and factor VIII as well as the antifibrinolytic factor (PAI-1), platelet abrasions, and endothelial dysfunctions. Grundy et al 2004, has shown that a fibrinogen, an acute-phase reactant protein like CRP, rises in response to a high-cytokine state.

It is characterized by increased plasma plasminogen activator inhibitor (PAI)-1 and fibrinogen, also associates with the metabolic syndrome. Fibrinogen, an acute-phase reactant like C reactive protien, rises in response to a high-cytokine state. Thus, prothrombotic and proinflammatory states may be metabolically interconnected. (Grundy et al 2004).

The study of plasminogen activator inhibitor-1 helps in better understanding of association between hemostatic markers and metabolic syndrome.

A study was conducted by Aso et al (2005) to determine whether plasma concentrations of thrombin-activatable fibrinolysis inhibitor (TAFI) in patients with type 2 diabetes were associated with components of metabolic syndrome

(MetS), including high-sensitivity C-reactive protein (hs-CRP), plasminogen activator inhibitor (PAI)-1, and LDL cholesterol.

The result indicated positive correlation between LDL cholesterol and plasma TAFI with type 2 diabetes mellitus.

Co-existence of metabolic syndrome and hypercholesterolemia accelerates inflammation and elevated TAFI and PAI-1, inhibits fibrinolysis. PAI-1 is an important risk factor for metabolic syndrome.

Three other biomarkers, CRP, IL6, and fibrinogen associate also importantly with the MetS cluster. These 4 biomarkers can contribute in the metabolic syndrome risk assessment (Kraja AT et al 2007).

7: Chronic Stress and Glucocorticoid (GC) Action.

Chronic hypersecretion of stress mediators, such as cortisol, in individuals with a genetic predisposition exposed to a permissive environment, may lead to the visceral fat accumulation as a result of chronic hypercortisolism, low growth hormone secretion, and hypogonadism.

GCs increase the activities of enzymes involved in fatty acid synthesis and promote the secretion of lipoproteins; induce the hepatic gluconeogenic pathway; promote the differentiation of preadipocytes to adipocytes, which could lead to an increased body fat mass; inhibit an insulin-stimulated amino acid uptake by adipocytes; and increase lipolysis or lipid oxidation which leads to the peripheral insulin resistance.

A correlation was observed between plasma cortisol levels, total urinary GC metabolites, and the number of features of the MetS among these patients. Both the secretion rate and the peripheral clearance of cortisol in these patients were positively correlated with the systolic blood pressure, and fasting glucose and insulin.These hormonal alterations may lead to a reactive insulin hypersecretion, an increasing visceral obesity, and sarcopenia, resulting in dyslipidemia, hypertension, and T2DM.

Systemic Effects of Metabolic Syndrome:

Renal: Microalbuminuria, hypofiltration, hyperfiltration, glomerulomegaly, focal segmental glomerulosclerosis, and chronic kidney disease [(F. Locatelli, P et al 2006).

Hepatic: Increased serum transaminase, nonalcoholic steatohepatitis (NASH), nonalcoholic fatty liver disease (NAFLD), hepatic fibrosis, and cirrhosis (100 K. D. Bruce et al 2009).

Skin: Acanthosis nigricans, lichen planus, systemic lupus erythematosus, burn-induced insulin resistance, psoriasis, androgenetic alopecia, skin tags, skin cancer, and acne inversa [T. Padhi and Garima 2013)

Ocular: Nondiabetic retinopathy, age related cataract-nuclear, cortical, posterior subcapsular; central retinal artery occlusion, primary open angle glaucoma, oculomotor nerve palsy, and lower lid entropion (R. Chopra, A. Chander, and J. J. Jacob 2012)

Sleep: Obstructive sleep apnea (OSA) (J. C. M. Lam and S. M. I. Mary 2010)

Reproductive system: Hypogonadism, polycystic ovarian syndrome (PCOS), and erectile dysfunction (A. Dokras et al 2005).

Cardiovascular system: Coronary heart disease (CHD), myocardial infarction (MI), and stroke (E. Standl 2005)

Cancers: Breast, pancreas, and prostrate (Y. Handelsman 2009).

CHAPTER: 4

GENETICS OF METABOLIC SYNDROME

The great variations in the susceptibility and age of onset in individuals with a very similar risk profile suggest a major interaction between genetic and environmental factors. It is recognized that some people who are not obese by traditional measures nevertheless are insulin resistant and have abnormal levels of metabolic risk factors. Considerable individuals and ethnic variations also exist in the clinical pattern of metabolic risk factors in obese/insulin resistant subjects.

It is likely that the expression of each metabolic risk factor falls partially under its own genetic control, which mainly influences the response to different environmental exposures. For example, a variety of polymorphisms in genes affecting lipoprotein metabolism are associated with the worsening of dyslipidemia among obese people.

Similarly, a genetic predisposition to the defective insulin secretion when combined with insulin resistance can raise the plasma glucose to abnormal levels.

According to the thrifty genotype hypothesis proposed by Neel in 1962 , individuals living in a harsh environment with an unstable food supply would maximize their probability of survival if they could maximize a storage of surplus energy.

Genetic selection would thus favour the energy-conserving genotypes in such environments. However, the selected genetic variations that were present during malnutrition would become unfavourable when nutrition improved. This

hypothesis assumes that the common genetic variants of thrifty genes predispose to MetS.

Another thrifty phenotype hypothesis was introduced by Hales and Barker in 1992.

According to this hypothesis, babies who experienced an intrauterine malnutrition may have adapted to a poor nutrition by reducing energy expenditure and becoming "thrifty."

Support for this hypothesis comes from the observed associations of low birth weight with later development of insulin resistance and T2DM in several populations.

There is differing opinion on the definitions and relatively low power of studies to detect the subtle effects of genetic variation, therefore genetics of metabolic syndrome is difficult to dissect.

The proposed candidate genes for metabolic syndrome are involved in energy storage and often support the thrifty phenotype (Speakman J R, 2006).

When the energy storing genetic variants are exposed to the westernized environment and abundance of high calorie food and physical inactivity, they may have become detrimental and cause the phenotype with metabolic disturbances observed in metabolic syndrome, including obesity and glucose intolerance.

Clustering of genes in families suggest a genetic component.

Candidate genes have a number of common variants which influence fat and glucose metabolism, these along with environmental factors can increase the susceptibility to the syndrome.

Among these, the genes for β3-adrenergic receptor, hormone-sensitive lipase, lipoprotein lipase, IRS-1, PC-1, skeletal muscle glycogen synthase, etc. appear to increase the risk of the metabolic syndrome. In addition, novel genes

may be identified by genome-wide searches. Among genes contributing to the metabolic syndrome, genes regulating lipolysis and thermogenesis still remain prime candidates (Groop L, 2000).

To date, no unifying genetic factors predisposing to metabolic syndrome have been clearly identified. Several genes have however been associated with at least two factors of metabolic syndrome and are therefore considered to be most promising candidate genes.

The adrenergic b- receptors (ADRB1,ADRB2 AND ADRB3) have been associated with obesity, hypertension and glucose intolerance and can therefore be considered as good candidates for predisposing to development of Metabolic syndrome (Bengtsson, K. et al 2001, Dionne, I.J. et al, 2002).

Several potential candidate genes have been suggested by their biologic relevance, such as genes in systems of energy balance, nutrient partitioning, lipid and insulin metabolism, lipolysis, thermogenesis, fuel oxidation, and glucose uptake in skeletal muscle.

These candidate genes include but are not limited to peroxisome proliferator-activated receptor (PPAR γ), adiponectin, CD36, β-adrenergic receptors, insulin receptor substrates (IRS), 11 β-hydroxysteroid dehydrogenase type 1 (11β-HSD1), CRP, tumor necrosis factor-α (TNF-α), calpain-10 (CAPN10), upstream transcription factor 1, and skeletal muscle glycogen synthase (Song Q, 2006).

CHAPTER: 5

BIOMARKERS OF METABOLIC SYNDROME AND PERIODONTAL DISEASES

Leptin :-

Leptin is an nitric oxide (NO) dependent vasodilator but also increases the peripheral vascular resistance and the sympathetic nerve activity (T. Shirasaka et al 2003). It is an adipokine mainly involved in the regulation of satiety and energy intake (D. C.W. Lau 2005). Levels of leptin in the plasma increase during the development of obesity and decline during the weight loss. It is expressed in levels proportionate to adipose mass, and though it is produced mostly by adipocytes, it is also produced by vascular smooth muscle cells, cardiomyocytes, and by placenta in pregnant women.

The functional leptin receptor is in the hypothalamus and the brain stem where it functions to increase energy expenditure and reduce appetite and neuroendocrine function.

The receptor is also found in other organs such as the heart, liver, kidneys, and pancreas; it is also present in the smooth muscle and endothelium of heart, brain vasculature, and myometrium

Most overweight and obese individuals have an elevated level of leptin that do not suppress appetite, or in other words, leptin resistance.

Leptin resistance is thought to be a fundamental pathology in obesity. Besides its effect on appetite and metabolism, leptin acts in the hypothalamus to increase the blood

pressure through activation of the sympathetic nervous system (SNS). (M. Carlyle, O. B. Jones, J. J. Kuo, and J. E. Hall, 2002).

High circulating levels of leptin are reported to explain much of the increase in the renal sympathetic tone observed in obese human subjects (N. Eikelis, M. Schlaich, A. Aggarwal, D. Kaye, and M. Esler, 2003).

Leptin-induced increase in renal sympathetic activity and blood pressure is mediated by the ventromedial and dorsomedial hypothalamus.

The concentration of plasma leptin is correlated with adiposity, and hyperlepidimia is indeed considered an independent cardiovascular disease risk factor (R.V. Considine et al 1996).

Leptin has a functional receptor (Ob-Rb), in the myocardium, and studies have shown a direct link between leptin and myocardial structural remodeling. There is controversy as to whether leptin causes or protects from left ventricular hypertrophy (LVH) as research has shown mixed results, though more suggest it contributes to LVH. Independent of conventional risk factors, studies have shown that leptin can predict myocardial infarction.

Leptin also affects vascular structure by promoting hypertension, angiogenesis, and atherosclerosis.

Leptin's role as a biomarker for metabolic syndrome has been researched in different populations.

Elevated leptin is associated with obesity, insulin resistance, myocardial infarction, and congestive heart failure. Yoshinaga et al found that leptin was the most sensitive marker for predicting metabolic syndrome (and cardiovascular risk) in elementary school children.

Lee et al found that leptin was elevated in postmenopausal women with metabolic syndrome. They found a positive correlation with leptin and abdominal obesity (one of the

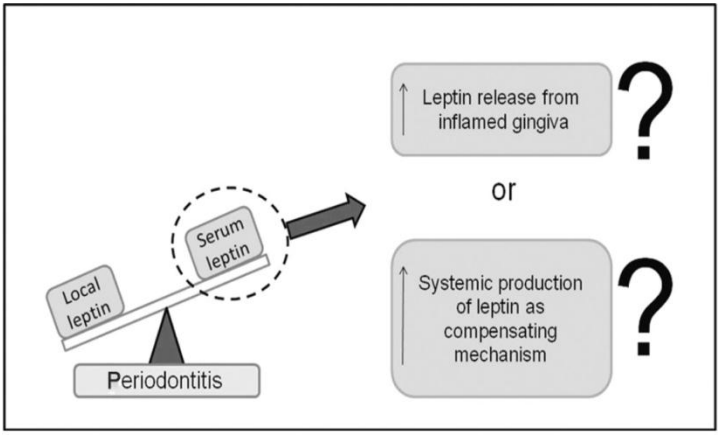
components of metabolic syndrome), and with the number of components of metabolic syndrome present.

A study of a Lebanese population, which focused on nondiabetic males over fifty years old, also found elevated leptin levels associated with metabolic syndrome.

This study found that leptin was strongly correlated with waist size, but was only weakly correlated with lipid profile, which disappeared with BMI adjustment.

Similar findings of elevated leptin associated with metabolic syndrome, independent of BMI, were found in a Korean population. In this study by Yun et al, serum leptin levels increased as the components of metabolic syndrome increased, regardless of obese and non-obese weight status, implying that reduction of leptin levels may be protective, regardless of weight loss.

Contrary to this, Martins et al, found a direct positive association between leptin and obesity, hyperinsulinemia and insulin resistance, but was only weakly related to other components of metabolic syndrome.



Increased serum leptin levels are seen in periodontitis.

Two putative explanations have been proposed.

First, gingival inflammation would result in vasodilation, which might increase the net rate of leptin removal from the gingiva and increase serum leptin levels.

The second hypothesis states that serum leptin levels rise as a body defense mechanism to counteract periodontal inflammation (according to Karthikeyan and Pradeep, 2007b).

Leptin negatively regulates the appetite and weight, mainly through a central mechanism involving the hypothalamus.

It also can interact with other hormones, such as insulin (Margetic et al., 2002; Guzik et al., 2006).

Obesity appears to be a condition of relative leptin resistance, with an elevated circulating level of leptin reported due to an enlarged fat mass (El-Haschimi et al., 2000). Moreover, there is some evidence that leptin is involved in the pathogenesis of atherosclerotic vascular disease (Wolk et al., 2004).

A decreasing leptin level in GCF and gingival tissue is associated with a more deteriorated periodontal status (Johnson and Serio, 2001), and smokers also show reduced GCF leptin levels (Bozkurt et al., 2006), suggesting a protective role of leptin for the periodontium.

The relationship between GCF and serum levels of leptin has been recently reported (Karthikeyan and Pradeep, 2007). GCF leptin levels are proportional to Body Mass Index (BMI).

In periodontitis, there is a significant negative correlation between GCF and serum leptin concentration, and these changes are significantly associated with increasing clinical attachment loss.

By contrast, a study of periodontitis and MetS (Borges et al., 2007) found a higher serum leptin level in healthy and chronic gingivitis individuals than in those with initial/moderate or advanced periodontitis.

Adiponectin:

Adiponectin, like leptin, is an adipose-derived plasma protein with widespread effects. However, unlike leptin, it is secreted exclusively from adipocytes. The different forms of adiponectin include low molecular weight trimer, middle molecular weight hexamer, and high molecular weight (HMW) (Lara-Castro C, Fu Y, Chung BH, Garvey WT 2007).

The HMW form is believed by many to be the more active form and has the most favorable metabolic effects on insulin sensitization and protection against diabetes.

Adiponectin has many functions, including anti-atherogenesis, insulin sensitization, lipid oxidation enhancement, and vasodilatation.

Therefore, it stands to reason that it is related to metabolic syndrome given its impact on all of these components.

It suppresses almost all processes involved in atherosclerotic vascular change: the expression of adhesion molecules in vascular endothelial cells, adhesion of monocytes to endothelial cells (via TNF-α inhibition), vascular smooth muscle cell proliferation and migration, and foam cell formation (via oxidized LDL inhibition) (Matsuzawa Y et al 2004);.

It has insulin-sensitizing activities, with high levels exerting a protective effect against type 2 diabetes in diabetes-prone individuals and low levels being an independent risk factor for future development of type 2 diabetes.

Levels of adiponectin are low in subjects with essential hypertension and in the obese, but adiponectin levels can be increased with weight loss.

A study of Japanese adults by Ryo et al showed that adiponectin levels were negatively correlated with waist circumference, visceral fat, serum triglycerides, fasting plasma glucose, fasting plasma insulin, and systolic and

diastolic blood pressure in males and females, and positively correlated with high density lipoprotiens. As the mean number of metabolic syndrome components increased, plasma adiponectin levels decreased.

They found that men had lower levels of adiponectin than women, since it may be part of the reason why women have a lower risk of coronary artery disease.

Gannage et al found adiponectin to be inversely correlated with metabolic syndrome, independent of BMI as other studies have also shown in the past.

Santaneimi et al studied a Finnish population and found decreasing adiponectin levels correlated with an increasing number of components of metabolic syndrome in both sexes, and this was once again independent of BMI.

Overall, the literature shows that adiponectin is inversely related to metabolic syndrome and the number of components present. However, many believe HMW adiponectin to be the more active form and Falahi et al suggest that HMW adiponectin may even be the most reliable biomarker for metabolic syndrome diagnosis.

Hara et al found that the ratio of HMW adiponectin to plasma adiponectin was an even better predictor of insulin resistance and metabolic syndrome.

Therefore, adiponectin, and preferably HMW adiponectin, should be considered on a panel of biomarkers for metabolic syndrome diagnosis.

Adiponectin levels remain relatively constant in normal circumstances (Trujillo and Scherer, 2005), but are decreased in obesity, insulin resistance, and diabetes, and in cardiovascular disease with increasing severity (Matsuzawa et al., 2004).

This reduction appears to precede these disorders, and low adiponectin levels have been shown to predict the development of insulin resistance and type 2 diabetes

(Spranger et al., 2003; Yamamoto et al., 2004). Thus, adiponectin has a key role in the development of MetS.

By an in vitro approach, adiponectin acts as a potent negative regulator of the osteoclast formation induced by Aggregatibacter actinomycetemcomitans lipopolysaccharide (LPS).

Therefore, adiponectin could exert an anti-inflammatory effect in periodontitis sites, and thereby have a negative influence over the onset and progression of periodontitis (Yamaguchi et al., 2007).

In humans, two recent studies (Furugen et al., 2008; Saito et al., 2008) have found that serum adiponectin levels tended to decrease in Japanese persons with periodontitis, not significantly.

Adiponectin levels were negatively correlated with mean attachment loss, but not mean probing depth or percentage of sites bleeding on probing.

Another study (Iwamoto et al., 2003) found that serum adiponectin levels did not change significantly after periodontal t Adiponectin is inversely associated with CVD risk factors such as blood pressure, low density lipoprotein cholesterol (LDL-C), and TGs.

Moreover, Pischon et al. have shown adiponectin to be a strong inverse independent risk factor for CVD.

Further, Fumeron et al. concluded that hypoadiponectinemia is associated with insulin resistance, hyperinsulinemia, and the possibility of developing T2DM, independent of fat mass.

The anti-inflammatory molecule, adiponectin, is negatively associated with the body weight, WC, TGs, fasting insulin, insulin resistance (HOMA-Homeostasis Model Assessment), BMI, and blood pressure, whereas a positive association exists between adiponectin and HDL-C (A. M. Xydakis, C. C. Case, P. H. Jones et al. 2004).

Its expressions and secretions are reduced by TNFα, possibly through a stimulated production of IL-6, which also inhibits adiponectin secretion.

Adiponectin is seen to be "protective," not only in its inverse relationship with the features of MetS but also through its antagonism of TNFα action (N. Ouchi, S. Kihara, Y. Arita et al 2000).

Leptin: Adiponectin Ratio

Studies have determined that the leptin: adiponectin ratio (LAR) is more beneficial than either alone. Falahi et al showed that a high LAR is a better biomarker than leptin or adiponectin alone for the diagnosis of metabolic syndrome.

A study of Japanese patients found that LAR was significantly and positively associated with the number of components of metabolic syndrome present, and the ratio was independently associated with each component of metabolic syndrome.

Cicero et al found the LAR to be strongly associated with metabolic syndrome, especially in males. The association was weaker in females since they had more elevated adiponectin levels, which is thought to be protective against metabolic syndrome.

Others postulate that the ratio difference between males and females is due to the difference in glucose and lipid metabolism.One limiting factor with using just adiponectin or leptin is that the difference between adiponectin and leptin tends to be small in the fasting vs postprandial state.

Therefore, one of the benefits of using the LAR is that it has the potential to assess insulin sensitivity and metabolic syndrome in the no fasting state.

Ghrelin:

Ghrelin is a neuroendocrine hormone secreted primarily by the stomach that stimulates appetite directly via activation of the GH secret agogue receptor 1a (GHSR-1a) in the

hypothalamus, and indirectly by increasing expression of orexigenic peptides, such as neuropeptide Y (NPY) (Varela L et al 2011).

It may also be protective of vasculature by antagonizing the effects of vasoconstrictors, such as endothelin 1, and promoting the effects of vasodilators, such as nitric oxide (NO). Furthermore, it can help to promote lipolysis via stimulation of hypothalamic AMP-activated protein kinase (AMPK).

Research into the vasoprotective and lipolytic properties of ghrelin is emerging and presents two pathways by which ghrelin can exert a protective effect against metabolic syndrome.

Metabolic syndrome is associated with lower levels of ghrelin, and progressively lower ghrelin levels are associated with increasing metabolic syndrome severity. Ghrelin levels have been shown to be higher in females than males. Low ghrelin levels have been associated with the components of metabolic syndrome including obesity, insulin resistance, and hypertension.

In obese patients, ghrelin levels are lower in insulin resistant patients compared to insulin sensitive obese patients.

Plasma ghrelin levels are also decreased in the healthy offspring of type 2 diabetes patients suggesting a genetic component to ghrelin regulation.

Ghrelin is implicated in endothelial function by preventing proatherogenic changes and improving vasodilation.

Tesauro et al assessed vascular function by measuring forearm blood flow in metabolic syndrome and control patients. They showed that exogenous ghrelin significantly reduced the vasoconstrictor effects of endothelin 1 and enhanced the vasodilator effects of NO in metabolic syndrome patients, but did not have a significant effect on vascular tone in control patients.

Given ghrelin's relation to each of the components of metabolic syndrome, to metabolic syndrome itself, and the potential to note abnormal levels in healthy individuals with genetic predispositions, it would be an effective biomarker for metabolic syndrome.

Plasminogen Activator Inhibitor – 1:

Plasminogen Activator Inhibitor-1 (PAI-1) is the primary of four serine peptidase inhibitors that functions to modulate extracellular matrix remodeling and fibrinolysis. It binds to and deactivates tissue plasminogens (tissue type plasminogen activator (tPA), urokinase plasminogen activator (uPA)).

Tissue type plasminogen activator is thought to be responsible for intravascular plasminogen activation, with fibrin regulating its activity, and uPA is responsible for plasminogen activation on migrating cells, with the uPA receptor regulating its activity on different cells.

Thus, PAI-1 can inhibit intravascular fibrinolysis and cell-associated proteolysis.

Under physiologic conditions, PAI-1 is secreted into the circulation or extracellular space by endothelial cells, adipocytes, vascular smooth muscle cells, platelets, or hepatocytes. Under pathologic conditions however, PAI1 is induced by many pro-inflammatory and pro-oxidant factors.

For example, when TNF-α, transforming growth factor beta (TGF-β), angiotensin II, glucocorticoids, and insulin are elevated, adipocytes are stimulated to increase PAI-1 levels.

Hypoxia and Reactive oxygen species(ROS) also increase PAI-1 levels. Elevated levels of PAI-1 consequently effect vasculature, inflammatory signaling, adiposity, and insulin resistance.

Aberrant PAI-1 levels are associated with several pathological diseases. For example, high levels are

positively correlated with thrombotic vascular conditions such as myocardial infarction and deep vein thrombosis. This is thought to be related to the inhibition of fibrin degradation and vessel wall remodeling.

It is thought to be a strong risk factor for coronary artery disease and some suggest it can be used as an independent risk factor for cardiovascular risk.

It has also been implicated in cancer angiogenesis and metastasis, wound healing, bacterial infections, rheumatoid arthritis, and chronic kidney disease.

The link between PAI-1 and metabolic syndrome has been long established with elevated levels being strongly correlated such that the more severe the metabolic syndrome, the higher the PAI-1.

Kraja et al showed that PAI-1 was strongly associated with the components of metabolic syndrome, including BMI, triglycerides and insulin resistance. Interestingly, several groups have found that PAI-1 levels are not associated with dyslipidemia but rather with the distribution phenotype of adipocytes: visceral adipose tissue primarily and ectopic fat in the liver.

PAI-1 can serve as a biomarker for ectopic fat storage. Like several of the other metabolic syndrome biomarkers, differences between the sexes have been noted, with the relationship being stronger in males than females.

PAI-1 levels decrease with calorie restriction, weight loss, decrease in body fat, and when insulin resistance improves.

Treatment with insulin-sensitizing drugs decreases PAI-1 in patients with diabetes and to some extent in otherwise healthy obese individuals.

Uric Acid:

Uric acid is an endogenously produced terminal degradation product of purine catabolism, formed by the liver and

excreted by the kidneys primarily and intestines secondarily.

Uric acid has antioxidant capacities extracellularly and can be responsible for 2/3 of the total plasma antioxidant capacity, where it chelates metals and scavenges oxygen radicals.

However, intracellularly, it has pro-inflammatory and pro-oxidant activity. It has been shown that uric acid is a circulating marker for oxidative damage in conditions like ischemic liver, atherosclerosis, diabetes, and chronic heart failure.

As a pro-oxidant, under ischemic conditions or as a result of tissue damage, uric acid oxidizes lipids, which results in inflammation that disrupts reverse cholesterol transport.

It also decreases the availability of nitric oxide, which results in less vasodilation and more reactive oxygen species (ROS). This, coupled with its ability to stimulate monocytes to produce TNF-α, creates a pro-inflammatory state found in metabolic syndrome.

Though its role in pathological diseases is not completely understood, uric acid likely causes systemic inflammation.

Hyperuricemia is a well-known risk factor for atherosclerotic events like myocardial infarction and stroke, and is associated with other cardiovascular risk factors like hypertension and dyslipidemia. Ishizaka et al also found a positive correlation between uric acid and BMI, blood pressure, and triglycerides, and a negative correlation with HDL-C.

Silva et al shows that uric acid levels are significantly elevated in males with abdominal obesity and females with abdominal obesity, low HDL-C, and hypertension.

Hyperuricemia is a marker of insulin resistance, as some studies have shown that decreasing insulin resistance by diet or medications decreases uric acid levels.

Among dietary causes of hyperuricemia, excess consumption of fructose via added sucrose or high-fructose corn syrup is of particular interest, as this dietary component has also been implicated in metabolic syndrome.

According to Khitan and Kim, fructose metabolism is initiated by an enzyme called ketohexokinase (KHK), also known as fructokinase. This ATP-dependent step in fructose metabolism lacks a negative feedback mechanism, so in the event of excessive fructose consumption, ATP is rapidly depleted and many of the dephosphorylated adenosine compounds are catabolized, resulting in increased uric acid.

Johnson et al demonstrated a link between fructose-induced hyperuricemia and an increased incidence of metabolic syndrome and some of its features, including obesity, hypertension, and insulin resistance.

Ishizaka et al investigated the relationship between uric acid and metabolic syndrome and found there to be a graded increase in the prevalence of metabolic syndrome with increasing uric acid in both sexes, though there are differences in the levels between males and females.

Levels of uric acid increase with age: in women of childbearing age, levels are lower, but increase to similar levels as males in post-menopausal conditions. Several studies have shown that uric acid levels are significantly elevated in individuals with metabolic syndrome, increases with the number of components of the condition, and are an indicator of worse cardiovascular risk profile. It is estimated that individuals with a high uric acid have an odds ratio of 1.6-fold higher for developing metabolic syndrome.

The close relationship between uric acid and the presence of metabolic syndrome has been demonstrated in children, adolescents,and adults.

Through a search of the published literature to date, uric acid appears to be the only metabolic syndrome biomarker studied in the West Virginian population.

Soukup et al studied salivary uric acid as a biomarker for metabolic syndrome and found the relationship to metabolic syndrome and each of its components similar to that of serum uric acid.

Similar to other studies, Soukup et al noted a stronger association between uric acid levels and metabolic syndrome in females than in males. This is a noninvasive and cost-effective method to diagnose and monitor metabolic syndrome.

Interleukin-6:

Interleukin-6 (IL-6) is a pro-inflammatory cytokine that plays a role in the natural inflammatory response.

It is often secreted by M1 macrophages as part of the normal inflammatory response against infection and injury. In metabolic syndrome, adipocyte dysfunction is frequently present and is associated with an increase in M1 macrophage population within adipose tissue.

This can result in increased secretion of IL-6 and other pro-inflammatory cytokines from adipose tissue. These pro-inflammatory cytokines can then act through a number of cell signaling pathways, including mTOR and Protein Kinase C (PKC) to induce insulin resistance.

Through its inflammatory properties it has been implicated in the endothelial cell damage within blood vessels that leads to vascular dysfunction and atherosclerosis.

Furthermore, IL-6 can cause aberrant insulin receptor activation, resulting in abnormal insulin signaling cascades, abnormal insulin action, and abnormal glucose metabolism.

Studies have shown that elevated levels of IL-6 are associated with metabolic syndrome and increasing levels are associated with more severe metabolic syndrome

(assessed by hypertriglyceridemia, hypertension, and fasting glucose levels). Similar to other biomarkers, IL-6 is also associated with each of the components of metabolic syndrome. In a study on postmenopausal women, elevated IL-6 was also associated with abdominal obesity, low HDL, and high triglycerides.

Indulekha et al found elevated IL-6 was associated with insulin resistance. In vivo animal studies have shown the effect of IL-6 on insulin signaling: the administration of IL-6 to mice resulted in impaired insulin signaling in muscle and liver tissue, leading to hyperglycemia and insulin resistance.

IL-6's close association with metabolic syndrome and each of its components suggests that it is an important factor in the progression of metabolic syndrome and would be a good addition to a biomarker panel.

Tumor Necrosis Factor-Alpha:

Tumor Necrosis Factor-Alpha (TNF-α) is a pro-inflammatory cytokine that is secreted by visceral adipose tissue, a common characteristic of metabolic

syndrome. Because metabolic syndrome is often characterized by adipocyte dysregulation, and these dysregulated adipocytes tend to secrete TNF-α, IL- 6, and other pro-inflammatory adipokines at higher levels, the central obesity often encountered in metabolic syndrome could be a risk factor for elevated TNF-α levels.

Furthermore, elevated TNF-α levels are associated with insulin resistance via its aberrant activation of the mTOR and PKC signaling pathways.

Its contribution to the various characteristics of metabolic syndrome suggest that TNF-α may be a significant contributor to the development and progression of its associated disease processes.

In a study of middle-aged adults with metabolic syndrome, elevated levels of TNF-α and other pro-inflammatory cytokines were associated with insulin resistance and hypertriglyceridemia. The TNF-α, IL-6, and leptin levels in these patients were higher than those levels in the control group, indicating that these cytokines directly correlated with metabolic syndrome.

It was hypothesized by Balasoiu et al that early detection of a patient's inflammatory status, including TNF-α and IL-6, could be useful in monitoring and early intervention for metabolic syndrome and its comorbidities [81]. In another study of metabolic syndrome patients with coronary artery disease (CAD), TNF-α levels were found to be significantly higher than the controls [82]. Indulekha et al also found elevated TNF-α levels to be significantly correlated with the presence of metabolic syndrome, and more so in those with insulin resistance.

Musialik et al demonstrated elevated levels of soluble TNF-α receptor (sTNFα-R), which is associated with increased TNF-α activity, in patients with metabolic syndrome with hypertension.

Because it exerts such widespread systemic effects, TNF-α may contribute to the various disease processes associated with metabolic syndrome and its components.

Interleukin-10:

Interleukin-10 (IL-10) is a predominantly anti-inflammatory cytokine that plays a role in modulating systemic inflammation.

Secreted by monocytes or M2 macrophages, one of its functions is to help promote normal tissue remodeling following an inflammatory response. One of the methods by which IL-10 moderates the inflammatory response is by inhibiting NADPH oxidase, and therefore the oxidative stress resulting from this enzyme.

This has been associated with aberrant insulin receptor substrate (IRS) activation and impaired insulin signaling.

Furthermore, the insulin signaling pathway can be dysregulated by abnormal levels of the pro-inflammatory cytokines IL-6 and TNF-α. IL-10 can restore normal insulin signaling by inhibiting NADPH oxidase-induced oxidative stress or by antagonizing the actions of IL-6 and TNF-α.

Regarding the role IL-10 plays in insulin signaling, a cross-sectional population study of elderly adults demonstrated that low levels of IL-10 are associated with insulin resistance and type 2 diabetes.

Furthermore, the study found that IL-10 levels inversely correlated with levels of total cholesterol, LDL, triglycerides, blood glucose and hemoglobin A1c, and positively correlated with HDL levels.

Additionally, in a study on mice treated with IL-6 to induce insulin resistance, in vivo administration of IL-10 demonstrated protection from the impaired insulin signaling that resulted from IL-6 administration, thereby restoring insulin sensitivity and normal glucose metabolism in liver and muscle tissue. Because it antagonizes the pro-inflammatory actions of IL-6 and TNF-α, which are both associated with metabolic syndrome and its comorbidities, IL-10 appears to exert a protective effect against increases in these cytokines.

The significance of IL-10 in relation to metabolic syndrome as a whole, rather than its components, however, is a little more complicated.

A study of obese children, found IL-10 levels to be elevated in metabolic syndrome, even after BMI was taken into account. Calcaterra et al proposed the elevated levels to be due to the first phase of a complex mechanism in the development of metabolic syndrome in children.

Esposito et al studied obese and non-obese women and found IL-10 to be elevated in obese women compared to

non-obese women but IL-10 levels were significantly lower in both obese and nonobese women with metabolic syndrome.

Others have also shown IL-10 levels to be significantly decreased in those with metabolic syndrome in both males and females. Some have shown that

IL-10 levels are significantly correlated with other cytokines like IL-6 and TNF-α. Adiponectin is correlated with IL-10 in patients with metabolic syndrome and not the general population.

This suggests that if both IL-10 and adiponectin are low, the risk of metabolic syndrome is likely greater. The use of multiple biomarkers in a panel would likely increase thesensitivity and specificity.

Oxidized LDL:

Oxidized LDL (OxLDL) is a product of lipid oxidation and can serve as a marker of oxidative stress.

Lipid oxidation contributes to the generation of reactive oxygen species (ROS). These products form components of OxLDL. Lipid oxidation products, ROS, and OxLDL in low concentrations can serve as signaling compounds for pathways of cellular antioxidants, including Heme Oxygenase (HO-1) and glutathione.

However, if the antioxidant capacity of the cell is dysfunctional, as is often seen in metabolic syndrome, then these compounds contribute to an oxidative cascade that eventually leads to cell damage and apoptosis.

This widespread cell damage and death can contribute to the vascular dysfunction commonly seen in metabolic syndrome, while the dysfunctional OxLDL can further contribute to dyslipidemia, presenting a risk factor for cardiovascular diseases, which are common morbidities associated with metabolic syndrome.

OxLDL contributes to atherosclerosis by invading and damaging the blood vessel endothelium. In addition to cardiovascular disease, elevated levels of OxLDL in adults are associated with obesity and insulin resistance, two common components of metabolic syndrome.

Levels of OxLDL are significantly elevated in metabolic syndrome patients and these elevated levels are further associated with reduced arterial elasticity, a risk factor for the development of CAD.

Other studies on children associated elevated levels of OxLDL with increased adiposity and insulin resistance. This study suggested that oxidative stress, measured by OxLDL levels, could be a contributing factor to insulin resistance, and that these changes can present early in life.

Additionally, a longitudinal study of young adults measured at baseline, 15 years later, and 20 years later demonstrated a significant positive correlation between OxLDL levels and the incidence of metabolic syndrome that arose between the 15-year and 20-year follow-ups.

The study also associated elevated Ox-LDL levels with central obesity, hyperglycemia, and hypertriglyceridemia, all of which are components of metabolic syndrome.

Free fatty acids:

Upper body subcutaneous adipocytes generate a majority of circulating FFA while an intra-abdominal fat content has been positively correlated with the splanchnic FFA levels which may contribute to the liver fat accumulation commonly found in abdominal obesity(J. M. Miles et al 2005).

Further, an acute exposure of skeletal muscle to the elevated levels of FFA induces insulin resistance by inhibiting the insulin-mediated glucose uptake, while, a chronic exposure of the pancreas to the elevated FFA impairs a pancreatic β-cell function (G. Boden 2001). FFAs increase fibrinogen and PAI-1.

PAI:

A serine protease inhibitor is secreted from intra-abdominal adipocytes, platelets, and the vascular endothelium (D. C.W. Lau,2005).

It exerts its effects by inhibiting the tissue plasminogen activator (tPA) and thus is considered as a marker of an impaired fibrinolysis and atherothrombosis.

Plasma PAI-1 levels are increased in abdominally obese subjects [58] and inflammatory states [59], thus, increasing the risk of an intravascular thrombus and adverse cardiovascular outcomes (H. P. Kohler et al 2000).

TNFα:

It is a paracrine mediator in adipocytes and appears to act locally to reduce the insulin sensitivity of adipocytes.

Evidence suggests that TNF-α induces adipocytes apoptosis [43] and promotes insulin resistance by the inhibition of the insulin receptor substrate 1 signalling pathway.

The paracrine action would further tend to exacerbate the FFA release, inducing an atherogenic dyslipidemia.

Plasma TNFα is positively associated with the body weight, WC, and triglycerides (TGs), while, a negative association exists between the plasma TNFα and High density lipoprotein–cholesterol (HDL-C).

Interleukin-6:

It is released by both adipose tissue and skeletal muscle in humans [52]. It has both an inflammatory and an anti-inflammatory action. IL-6 receptor is also expressed in the several regions of the brain, such as the hypothalamus, in which it controls an appetite and energy intake (K. Stenlof et al 2003).

It is a systemic adipokine, which not only impairs insulin sensitivity but is also a major determinant of the hepatic production of CRP.

IL-6 is capable of suppressing lipoprotein lipase activity. It has been shown to be positively associated with BMI, fasting insulin, and the development of T2DM and negatively associated HDL-C

Paraoxonase:

Paraoxonase-1 (PON-1) is a multipurpose antitoxic and antioxidant enzyme and is believed to contribute to the antioxidant and anti-inflammatory properties of HDL.

In particular, it can reduce lipid peroxidation and protect LDL and tissue from oxidative stress. Levels of PON-1 activity correlate with systemic antitoxic and antioxidant capacity, whereas oxidative stress and lipid peroxidation are associated with the onset and progression of metabolic syndrome and some of its comorbidities, particularly vascular dysfunction (resulting from OxLDL).

In low concentrations, OxLDL and ROS serve as signaling compounds in cellular antioxidant pathways, which serve to improve cellular protection mechanisms in the face of oxidative stress.

However, if these antioxidant pathways are overwhelmed from excessive oxidative stress, the oxidative cascade can progress to cell damage and death, resulting in tissue damage, particularly in vascular endothelial tissue.

Because of its antioxidant properties, PON-1 may play a role in managing the normal oxidative signaling pathway, and it could serve as a useful biomarker in assessing antioxidant capacity, and by extension, the propensity for systemic inflammation and vascular dysfunction.

In a study of lean, overweight and obese adolescents, decreased levels of PON-1 were associated with central obesity and metabolic syndrome.

Additionally, lower levels of PON-1 were associated with hypertension, hypertriglyceridemia, insulin resistance, impaired glucose tolerance, and increased oxidative stress.

Another study of women withand without metabolic syndrome showed a negative correlation between PON-1 levels and the presence of CAD in metabolic syndrome patients.

CAD is a significant comorbidity in metabolic syndrome, and lower levels of PON-1 could be suggestive of a diminished effectiveness of HDL to attenuate CAD development and progression.

Martinelli et al also found that decreased PON-1 levels were associated with metabolic syndrome, with an inverse correlation between PON-1 levels and the severity of metabolic syndrome and its comorbidities.

The literature suggests that PON-1, via its antioxidant properties, could play an important role in attenuating the components of metabolic syndrome that arise and progress as a result of oxidative stress.

CHAPTER- 6

ASSOCIATION OF METABOLIC SYNDROME WITH PERIODONTAL DISEASES

METABOLIC SYNDROME AND PERIODONTITIS:

Obesity plays a central role in metabolic syndrome and is an important risk factor for diabetes mellitus and arteriosclerotic diseases. Many studies have reported that obesity is also associated with periodontal disease and in particular, a strong association between visceral fat obesity and periodontitis has been demonstrated.

Moreover, longitudinal studies reporting an increased risk of periodontal disease progression among obese people suggest the possibility that obesity affects periodontal status.

Adipose tissue secretes various adipocytokines, including adiponectin, leptin, and human tumor necrosis factor-α (TNF-α), as physiologically active substances, and the abnormal production of adipocytokines associated with obesity and metabolic syndrome leads to insulin resistance and arterial stiffening.

An increase in TNF-α in blood due to obesity triggers periodontal disease via promotion of inflammation in periodontal tissue, and TNF-α produced due to periodontal tissue inflammation induces insulin resistance, which works negatively in the context of blood glucose metabolic regulation.

It has been shown that the serum leptin concentration is higher in obese individuals than in thin individuals, and in individuals with periodontal disease, the level of leptin is low in gingival crevicular fluid and high in serum.

Moreover, the serum leptin concentration in individuals with periodontitis has been shown to correlate with interleukin-6 (IL-6) and C-reactive protein (CRP), and treatment of periodontitis decreased serum leptin, IL-6, and CRP56, suggesting that the association between metabolic syndrome and periodontal disease involves adipocytokines playing a role as a mediator.

It has been suggested that diabetes mellitus and periodontal disease have a bi-directional relationship.

The diagnostic criteria for metabolic syndrome include hyperglycemia, and in patients with type 2 diabetes mellitus, those who apply to two of the four items of the NCEPATP III diagnostic criteria other than hyperglycemia have been shown to have a high periodontitis risk.

Moreover, individuals with more extensive periodontitis showed a greater increase in HbA1c over a five year period, and this tendency was particularly prominent in those with a high CRP value. These results suggest that chronic inflammation caused by periodontal disease may induce abnormal glucose metabolism, consequently leading to diabetes mellitus.

With regard to the mechanisms underlying the association between metabolic syndrome and periodontal disease, the formation of oxygen free radicals, oxidative stress, lipid peroxidation products, and advanced glycation end products have been indicated to play an important role.

In fact, one study using a mouse model of diabetes mellitus showed that alveolar bone resorption, which occurs as a complication of diabetes mellitus, is possibly caused by local periodontal oxidative stress.

On the other hand, periodontal treatment for periodontitis patients with type2 diabetes mellitus was effective in improving metabolic regulation, such as a decrease in blood glucose levels or HbA1c. Adiponectin decreases blood glucose by improving insulin resistance, which is one of the

characteristics of type 2 diabetes mellitus, and is also said to improve lipid metabolism abnormalities.

Periodontal treatment in patients with type 2 diabetes mellitus, therefore, not only improves their periodontal status but also leads to decreased HbA1c and increased serum adiponectin.

In these contexts, it might be possible to decrease the risk of diabetes mellitus by performing anti-inflammatory periodontal treatment in individuals with abnormal glucose metabolism or metabolic syndrome.

It is a well established fact that the primary etiological agent in periodontal disease is bacterial plaque. The toxins and the enzymes produced by the bacterial plaque elicit inflammatory and immunologic changes in the periodontal tissues at both cellular and molecular levels.

Periodontitis is a common chronic infection of the adult population characterized by an exaggerated gingival inflammatory response against a pathogenic bacterial microflora, resulting in alveolar bone loss and eventually tooths loss.

Periodontitis is associated with systemic alterations like low-grade inflammation Dyslipidemia, glucose intolerance, endothelial dysfunction.

Lipopolysaccharide derived from periodontal pathogen, Porphyromonas gingivalis which increases the circulating tumor necrosis factor-α which induces the insulin-resistance and atheromatous changes.

In metabolic syndrome there is an elevation in circulating proinflammatory cytokines and a procoagulant state exists with elevation of C-reactive protein and fibrinogen.

Both periodontitis and metabolic syndrome are associated with systemic inflammation and insulin resistance with elevation in WBC count as a result of body's defence mechanism.

Considering chronic inflammation as the basis for the association between periodontal disease and metabolic syndrome they can be linked through a common patho physiological pathway.

PERIODONTAL DISEASE AND OBESITY:

Obesity is defined by the body mass index as greater than 30.0kg /m². Cytokines and hormones from the fat tissue plays an important role in the pathogenesis.

Tumor necrosis factor-alpha, leptin, adiponectin and resistin modulates the periodontal response.

Leptin controls the appetitie, regulates the immune response and the production of inflammatory cytokines. The obesity is associated with the reduction of the sensibility to the effects of the leptin which stimulates the immunological system.

In periodontitis there is a negative correlation among the levels of leptin in the gingival crevicular fluid. Adipocytes secreting proinflammatory cytokines may be the molecules linking to the pathogenesis of periodontal infection.

Cytokines and hormones from the fat tissue may play an important role.

The fat tissue, especially the visceral type, acts as an important endocrine organ secreting several bioactive substances, such as adipocytokines. Among the most important ones are the tumor necrosis factor-alpha, leptin, adiponectin and resistin, which may modulate the periodontal response.

The obesity is associated with the reduction of the sensibility to the effects of

the leptin, which stimulates the immunological system since it increases the production of cytokines and the phagocytosis by the macrophages.

It is a specific hormone of the adipocyte acting as a signaling molecule in the hypothalamus to complete the feedback of the lipostatic theory of weight control.

In periodontitis, there is a negative correlation among the levels of leptin in the gingival crevicular fluid (GCF), significantly associated with the increasing of the loss of clinical insertion.

Two explanations have been proposed for the increase of the serum levels of leptin in periodontitis: firstly, the gingival inflammation would result in vasodilatation, which would increase the serum levels of leptin; secondly, the serum levels of leptin would increase as a defense mechanism of the body, to fight the periodontal inflammation.

In the inflammatory periodontal disease, the leptin regulation still needs to be further studied, especially regarding to the epidemiological association between obesity and periodontitis.

Other substance secreted by the fat tissue is the adiponectin. Unlikely to other hormones from the fat tissue, the levels of adiponectin are reduced in people with obesity, insulin resistance or diabetes type 2, acting as an inhibitor of the inflammatory process.

Experimental models have suggested that adiponectin plays a mediator role in inflammatory diseases, acting as a predictor of the insulin resistance and of the diabetes type 2.

Resistin is a specific hormone from the fat tissue recently discovered and it directly induces the insulin resistance in the muscle and liver.

Resistin had its role in periodontitis proved by two studies, in which the serum levels were higher in people exhibiting periodontitis than in control subjects, showing a positive correlation with bleeding on probing.

Moreover, the releasing of the tumor necrosis factor-alpha both by the liver and the periodontal tissues in response to LPS, endotoxins of gram negative periodontal pathogens, would contribute to the insulin resistance.

Data of a study in humans have suggested that the reduction in the serum concentration of LPS may contribute to the control of the metabolic diseases.

A study investigated the role of oral bacterias in the obesity epidemic.

The bacterial population in the saliva of overweight women and normal weight women were measured. The percentage of Selenomonas noxia was capable of identifying 98.4% of the overweight women, suggesting the possibility that the bacterial species act as biological indicators for the development of weight gain and participate in the etiology of obesity.

PERIODONTITIS AND HYPERLIPIDEMIA:

The alterations in immune cell phenotype due to serum lipids and elevation in serum pro-inflammatory cytokines such as TNF-α and IL-1β through periodontitis as a chronic gram (-) infection verified substantial evidences supporting the bidirectional relationship

Lipid metabolism can be altered by chronic and acute periodontal infections which are involved in the plasma concentrations of unregulated cytokines and hormones. The main features of this catabolic state are lipid oxidation and elevated free fatty acids, triglycerides and low density lipoprotein (LDL) cholesterol.

Studies in humans and animals have shown a number of cytokines such as tumor necrosis factor alpha (TNF-α) and interleukin-1 beta (IL-1β) are produced in response to systemic Gram negative LPS exposure.

It is believed that these cytokines exert effects on lipid metabolism by influencing production of other cytokines,

altering hemodynamic/aminoacid utilization of various tissues involved in lipid metabolism, or modifying the hypothalamic-pituitary-adrenal axis increasing plasma concentrations of adrenocorticotropic hormone, cortisol, adrenaline, noradrenaline and glucagon.

These elevations in serum lipids are thought to arise from enhanced hepatic lipogenesis, increased adipose tissue lipolysis/blood flow, increased synthesis or reduced clearance of triglyceride, and reduced clearance of LDL due to reductions in lipoprotein lipase activity.Thus, any condition producing elevations in serum TNF-α and IL-1β which are increased in periodontitis has potential to cause hyperlipidemia.

Lipids may interact directly with the macrophage cell membrane, interfering with membrane-bound receptors and enzyme systems, altering macrophage gene expression for pro-inflammatory cytokines such as TNF-α and IL-1β and essential polypeptide growth factors such as platelet-derived growth factor (PDGF), transforming growth factor beta 1 (TGF-β1) and basic fibroblast growth factor (bFGF).

Additionally, serum lipids, whether induced by diabetes, or diet increase polymorphonuclear leukocyte (PMN) production of pro-inflammatory cytokines and inhibit macrophage production of essential polypeptide growth factors impairing the wound healing process.

Fatty acids may be incorporated into the plasma membrane after dietary lipid administration, so that the composition of lipids in this cellular structure will reflect the composition of dietary lipids.Because of this incorporation, the phospholipid profiles associated with plasma membrane of lymphocytes, monocytes/macrophages or polymorphonuclear cells may be altered by dietary lipids.

Diets including polyunsaturated fatty acids, such as eicosapentaenoic or docosahexaenoic acids, suppress the mitogenic response of lymphocytes to a greater extent than diets rich in saturated fatty acids.

Fatty acids may regulate cytokine production and in fact cytokine modulation by fatty acids seems to be responsible for the reduction of lymphocyte proliferation in both animals and humans.

Cytokines such as IL-1 and TNF are important mediators of inflammation and dietary fatty acids have been demonstrated to be substances capable of reducing the pro-inflammatory response induced by IL-1 and TNF.

It has been reported that unsaturated fatty acids increase phagocytosis which is an important mechanism in many cells for the elimination of microorganisms or foreign particles.

Mechanisms involved in fatty acid modulation are membrane fluidity, production of lipid peroxides, eicosanoid synthesis and influence on gene regulation. As a result of changes in the phospholipids fatty acid composition due to dietary lipid manipulation, the fluidity of the cell membrane may change.

Hyperlipidemia, arising from a high-fat diet or metabolic disorders such as type 2 diabetes, has a dysregulatory effect on immune system cells and on wound healing and as a result, it increases the susceptibility to periodontitis and other infections.

This condition needs a particular threshold level of circulating lipids for every individual, above which can lead to this dysregulatory effect within the gingival mucosa and elsewhere.

It has been reported that consumption of a typical high-fat American breakfast (fried eggs, bacon, potatoes) or a defined saturated-fatrich meal (i.e. ice cream) leads to functional abnormalities in PMNs.

A protective role for PMNs in the early response to periodontal infection is supported by compelling experiments in nature, wherein subjects with impairments of PMN function have more acute and severe periodontitis.

So, PMNs primed by endotoxin or other activating agents, including dietary lipids may play a major role in the pathogenesis of periodontitis. Hyperlipidemia is known to cause a hyperactivity of white blood cells.

Hyperactivity of white cells, e.g., increased production of oxygen radicals, have been shown to be frequently associated with progressive periodontitis in adults.In animals feeding a cholesterol-rich diet have caused to periodontitis.

In an animal model, Maglakelidze et al reported significant changes in extracellular matrix and gingival mucous cells as well as in microcirculatory bed components in hypercholesterolemia.

Hypercholesterolemia damages endotheliocytes, subendothelial zone and basal membrane permeability. The contact of lymphocytes and plasmocytes with the vascular wall confirms the trigger role of the vascular factor in damaging of periodontal complex.

There are several studies which report significant association between plasma lipid levels and the severity of the periodontal disease.

While some authors mentioned that there were significant correlations between periodontal status and cholesterol levels, others indicate that there were significant associations between triglyceride level and periodontal disease.

The studies which trying the effect of periodontal therapy on serum lipids and lipoprotein associated inflammatory mediators also suggested that the treatment of periodontal disease have beneficial effects on lipid metabolism.

In one study conducted in systemically healthy subjects with periodontitis, Pussinen et al stated that periodontitis is associated with macrophage activation via increased serum LPS concentration.

Additionally, there was a significant increase in the ratio of HDL/LDL after periodontal treatment in this study.

In another study, Pussinen et al reported that there were statistically significant decreases in CRP and serum amyloid A levels after periodontal treatment in systemically healthy subjects with periodontitis. That study also suggested that periodontitis diminishes the anti-atherogenic potency of HDL and increase the risk for coronary heart disease.

Lösche et al evaluated 32 patients with moderate to severe periodontitis before and 3 months after local periodontal treatment and they reported that treatment of periodontitis caused a significant reduction in the serum activity of lipoprotein-associated phospholipase A2 which is believed to be an independent cardiovascular risk factor.

In a similar study, 65 subjects presenting with severe (probing pocket depth greater than 6 mm and marginal alveolar bone loss greater than 30%), generalized (at least 50% of teeth affected) periodontitis were assessed and the 3 groups consisted of untreated control; standard periodontal therapy; and an intensive periodontal treatment including standard periodontal treatment with adjunctive local delivery of minocycline.

In that study both standard periodontal therapy and intensive periodontal therapy resulted in significant reductions in serum CRP compared with the untreated control and the intensive periodontal therapy group also showed a decrease in total and LDL cholesterol after 2 months following the periodontal treatment.

Higher serum levels of total cholesterol, LDL-C and triglycerides have been found in subjects with periodontal disease and hyperlipidemic patients have a significantly higher percentage of sites with probing depth greater than 3.5 mm than subjects with normal metabolic status.

The interrelationship between periodontitis and hyperlipidemia provides an example for systemic disease predisposing to oral infection, and once the oral infection is established, it exacerbates systemic disease.

PERIODONTITIS AND CARDIOVASCULAR DISEASE:

Systemic and local chronic inflammatory states, such as periodontitis and MetS, are characterized by an elevated presence of acute-phase proteins such as C- reactive protiens and fibrinogen, which represent a decisive contribution to the insurgence of atherosclerosis and CVD. Viceversa, the reduction of periodontal inflammation through plaque control, systemic antibiotics, scaling, and root planning seems to decrease CRP levels in patients suffering from MetS, reducing the risk of CVD (López NJ 2012).

Over the past 2 decades, inflammation has emerged as an integrative CVD factor. Inflammation can operate in ‘‘all stages of this disease from initiation through progression and, ultimately, the thrombotic complications of atherosclerosis.

Higher quantiles of CRP, measured by a high-sensitivity assay (hsCRP), predict future acute myocardial infarction and unstable angina pectoris and the onset of systemic arterial hypertension, diabetes mellitus, and stroke, independent of blood lipid levels.

CRP itself, beyond serving as a biomarker, have a role in endothelial cell dysfunction.

The erythrocyte sedimentation rate, chemokines, and cytokines including IL-6, IL-8, IL-10, IL-18, TNF-a, and monocyte chemoattractant protein–1 also are frequently abnormal in patients with acute coronary syndromes and in many other conditions.

Periodontal pathogens draw lymphocytes in an attempt to stem infection through phagocytosis and killing, causing

augmented production of ROS, which ends in a situation of oxidative stress. The presence of ROS promotes chemotaxis and recruits inflammatory mediators from the liver, causing periodontal destruction and favoring the making of endothelial atheromas.

Periodontal pathogens are also able to invade the endothelium and atheromas; in fact, oral infection, being a source of bacteria, is associated with CVD.

There are several theories that attempt to explain the correlation between periodontitis and CVD ((López NJ 2012).

One theory is the **bacteriological theory**, according to which oral pathogens, such as P. gingivalis, invade the systemic circulation and by means of the virulence factors, such as fimbriae, are able to invade the atheromatous plaques.

These bacteria can activate endothelial cells through TLR4 and induce apoptosis in these cells, disrupting the mechanisms of cell adhesion.

The **inflammatory theory** holds that in the course of periodontitis, gingival cells produce inflammatory mediators such as TNF-α, IL-6, PGE-2, and MMPs that locally promote tissue destruction and, once in the circulation, stimulate endothelial cells to produce other mediators such as monocyte chemotactic protein (MCP-1), macrophage colony stimulating factor (MCSF), intercellular adhesion molecule (I-CAM), vascular cell adhesion molecule (V-CAM), P-selectin, and E-selectin. These cytokines accelerate the formation of atheroma.

The third theory is the **autoimmune theory**, according to which antibodies against bacterial antigens may also react against endothelial protein, causing their destruction and therefore the arterial lesion.

It is of note that during the development of periodontitis, in the attempt to remove causal agents, hyperinflammation is

triggered, attracting numerous neutrophilic granulocytes, which, through the production of digestive enzymes during phagocytosis and killing, favor the production of ROS and the consequent constant release of inflammatory mediators with direct bacterial action damage on periodontal tissue.

In addition, it seems that in people suffering from periodontitis, pathogen bacteria, endotoxins, and inflammatory mediators cause leucocytosis and increased lipidic metabolism, with an increase of cholesterol and hepatic triglycerides favoring the risk of CVD. Furthermore, a systemic increase of oxidative stress caused by periodontal disease seems to promote LDL oxidation. LDLs are cholesterol carriers with proinflammatory and pro-atherogenic activity.

Periodontal treatment by scaling and root planning, and dental care instruction seem to reduce the circulating oxLDL level and, consequentially, the risk of the onset of CVD.

Systemic and local chronic inflammatory states, such as periodontitis and MetS, are characterized by an elevated presence of acute-phase proteins such as CRP and fibrinogen, which represent a decisive contribution to the insurgence of atherosclerosis and CVD.

Viceversa, the reduction of periodontal inflammation through plaque control, systemic antibiotics, scaling, and root planning seems to decrease CRP levels in patients suffering from MetS, reducing the risk of CVD.

The incidence of atherosclerotic CVD events increases in patients with chronic inflammatory diseases, in addition to periodontitis, including rheumatoid arthritis, psoriasis, systemic lupus erythematosus, some types of infections, mainly infections of the respiratory tract and urinary tract.

Arterial inflammation, along with arterial stiffness and remodeling, may be a factor in systemic arterial hypertension, particularly in obese patients.

Evidence supporting the role of inflammation in atherosclerotic events gained support with the findings of Justification for the Use of Statins in Primary Prevention: An Intervention Trial Evaluating Rosuvastatin (JUPITER), in which treatment with rosuvastatin significantly reduced the incidence of cardiovascular events in subjects with lower levels of LDL cholesterol but with mild chronic inflammation indicated by levels of hsCRP >2 mg/L.

The precise role of inflammation as a direct, causative factor in chronic atherogenesis and in the acute complications of atherosclerosis remains an area of intense current investigation.

Multiple studies, however, support two biologically possible mechanisms:

(1) Moderate to severe periodontitis increases the level of systemic inflammation, a characteristic of all chronic inflammatory diseases, and periodontitis has been associated with increased systemic inflammation as measured by hsCRP and other biomarkers. Treatment of moderate to severe periodontitis sufficient to reduce clinical signs of the disease also decreases the level of systemic inflammatory mediators.

(2) In untreated periodontitis, 108 to 1012 gram-negative bacteria may be found in periodontal pockets surrounding each diseased tooth and in approximation to ulcerated epithelium, and bacterial species found predominantly in the periodontal pockets also have been found in atheroma. (Haraszthy et el J Periodontol 2000)

An indirect relationship between periodontitis and atherosclerotic CVD is the many shared risk factors that commonly occur in the two diseases. Thus, many factors, especially cigarette smoking,5-10 are confounders in determining their relative importance in this relationship.

There is evidence that periodontal disease is related to CVD in young (aged £55 years) non-smokers.91 In addition to

tobacco use, the following risk factors are common to periodontitis and CVD:

(1) Diabetes mellitus: there are no reported interventional studies designed to ascertain whether periodontal disease prevention or treatment reduces CVD prevalence or mortality in patients with either type 1 or type 2 diabetes mellitus.

(2) Obesity: systemic inflammation, defined by increased circulating TNF-a, is associated with obesity and periodontitis and has been(Genco RJ et al 2005) proposed as a mechanism for the connection between these conditions.

(3) Lipids: a case-controlled study showed that periodontitis is associated with elevated plasma triglycerides and total cholesterol.

A large epidemiologic study in the United States determined that total serum cholesterol and plasma levels of CRP and fibrinogen are elevated in patients with periodontitis (Wu T et al 2000)

(4) Hypertension: an epidemiologic study in Sweden of >4,000 subjects showed an increased prevalence of hypertension in patients with periodontitis. Smaller studies in the United States found that, after adjusting for confounders, hypertension was more prevalent in patients with severe alveolar bone loss.(Holmlund A 2006), and significantly more hypertension occurs in patients with periodontitis compared with populations with little or no periodontal disease (Engstrom S 2007).

Systemic inflammation, a feature of hypertension, as evidenced by increased hsCRP plasma levels in patients with prehypertension and patients with established hypertension, may link these two conditions (Sesso HD et al 2003).

DIABETES AND PERIODONTAL DISEASE:

Diabetes, a pathology that is extremely widespread, involves an adulterated homeostasis in the glucose metabolism. Two types of diabetes exist: type 1 diabetes and type 2 diabetes (T2D). Either typology of diabetes, if not controlled, is a risk factor for periodontitis.

The first type affects young people and sets in from childhood. The pathological mechanism is that β cells of Langerhans are unable to produce insulin. Consequently, glucose tends to accumulate in the tissues and the blood.

The pathology develops in middle age.T2D is the most common type and consists in an adulterated insulin cellular response. The onset of T2D is associated with the recruitment of proinflammatory cytokines that are involved in the onset of the disease and related complications such as dyslipidemia and atherosclerosis, contributing to the onset of microvascular and macrovascular complications.

Patients with periodontitis show a higher risk of ketoacidosis, retinopathy, and neuropathy than do diabetic patients without periodontal disease. In addition, diabetic patients with neurological complications have severe gingivitis compared with diabetic individuals without this complication.

Many studies demonstrate a biological relation between diabetes and periodontitis, as tested relations exist between glycated hemoglobin, a diabetic marker, and periodontal parameters, and between plasmatic lipid peroxide, an index of oxidative stress, and periodontal markers.

Prolonged hyperglycemia associated with diabetes causes the formation of advanced glycation end-products (AGE). AGEs are physiologically produced by the organism, but in conditions of hyperglycemia or augmented oxidative stress their presence is largely augmented.

AGEs result from reversible glycation reactions, that is, the addition of sugars on the polypeptide chain of proteins, lipids, or nucleic acids.

Whether an enzyme attends or not in the glycation reactions, we can have an enzymatic or nonenzymatic glycation. Furthermore, more resistant proteins such as interstitial or vassal collagen can undergo a nonenzymatic glycation.

Several cells, such as endothelial, muscular, and immune cells, possess specific AGE receptors, called RAGE. In fact, a confirmation of AGE activity against periodontal tissue is proved by an elevated presence of RAGE in the periodontal compartment.

AGEs have deleterious effects for the organism and, being resistant to proteolytic digestion, are difficult to eliminate and tend to accumulate, expressing their harmful effect. AGE-degradation products are chiefly expelled through urine.

AGEs are substances able to promote cytokine production by macrophages such as TNF-α and IL-6, and to stimulate hepatic secretion of acute-phase proteins such as CRP, fibrinogen, plasminogen activator/inhibitor, and serum amyloid A, also correlated with oral infection and cardiovascular diseases, especially in patients suffering from periodontal diseases.

AGEs also promote monocyte migration and increase endothelial permeability, fibroblasts, and muscular cell activity. In addition,AGEs can bind collagen, which if modified alters basement membrane structure.

This gives to an inhibition of oxygen diffusion and tissue oxygenation, diminished waste removal, altered immune mediators, and migration that causes an adulterate inflammatory response, which results in inadequate tissue recovery.

AGEs also lead to the rapid expansion of energy in the respiratory polymorphonuclear neutrophils (PMN), and this causes increased damage to periodontal tissues and some changes in bone metabolism, especially on repair, also reducing the production of the extracellular matrix.

The course of the periodontal illness is due to basic neutrophilic activity that results in an exaggerated immune response and an uncontrolled ROS production.

These cause local and peripheral oxidative damage, both directly, through oxidative injury, and indirectly, by means of redox-sensitive gene transcription factors.

Nuclear factor kappa B and activating protein 1 are activated,triggering an inflammatory mediator cascade and quick cellular aging.

Diabetic patients with severe periodontitis have demonstrated a reduced chemotaxis of PMN compared with healthy subjects, or patients with less aggressive periodontitis, and an altered control of apoptosis, which is followed by an accumulation of PMNs in the periodontal tissues and therefore of MMPs and ROS.

The lack of glycemic control has also been associated with alterations in the oral mucosa barrier. The presence of diabetes seems to increase inflammation in the periodontium, so much so that in the gingival crevicular fluid there are increased levels of PGE2 and IL1-β compared with parodontopatic normoglycemic patients. Moreover, the presence of diabetes mellitus prolongs the inflammatory response to P. gingivalis, causing an increase in the production of TNF-α.

In synthesis, diabetes appears correlated to the onset of periodontal diseases, both through changes in the host immune response and through anomalies in the collagen metabolism. Recently, different molecules have been investigated for the treatment of diabetes.

Decursin (De), an active component of Angelica gigas, known to exert anticancer and neuroprotective effects, was recently studied for its antiobesity and antidiabetic potential. De treatment resulted in the inhibition of adipocyte differentiation and expression of fatty acid synthase.

Administration of De along with a high-fat diet (HFD) significantly reduced the secretion of HFD induced adipocytokines such as leptin, resistin, and IL-6 (Hwang JT et al 2012).

Periodontal inflammation can later give rise to a systemic inflammatory state. A recent study suggested a concrete relationship between severe periodontitis and systemic oxidative stress with a reduction in antioxidant systemic defenses. Moreover, it seems that after a periodontal treatment, a transitory inflammatory acute response occurs with a concomitant increase of systemic oxidative markers.

In periodontal diabetic individuals suffering from T2D, there is an augmented rate of oxidative systemic markers and a diminished plasma small-molecule antioxidant capacity. These patients also show reduced β-cell activity. Therefore, periodontitis enlarges oxidative stress– mediated dysfunction in β-cells of Langerhans.

Even in periodontitis, the mediated response of the host, in the presence of bacterial infections, results in an increased release of systemic inflammatory mediators.

The toll-like receptors (TLR), the receptors for the Ig superfamily (TLR4), and RAGE are implicated in the intensification of the systemic immune response during chronic diseases, such as diabetes and periodontal disease. Fibroblasts, macrophages, and epithelial cells present in the periodontium possess both RAGE and TLR4. It seems that hyperglycemia can promote the expression of these receptors in the periodontal district and increase the response to their ligands, favoring the accumulation of these ligands.

Several studies have shown how chemical and mechanical periodontal treatment may improve glycemic and lipidic control in time. It seems that periodontal therapy leads to a reduction in the glycated hemoglobin (HbA1c) plasma rate and to a better lipidic profile.

HYPERTENSION AND PERIODONTITIS:

Hypertensives suffering from MetS show increased oxidative stress and compromised antioxidant activity in plasma and cells. In addition, obesity and overweight are strictly related to hypertension. In fact, weight loss determines a diminished blood pressure independent from sodic diet (Chaves FJ et al 2007).

Hyperglycemia and hypertension are strictly related. Hyperglycemia provokes an increased stimulation of a sympathetic nervous system that causes vasoconstriction and increased sodium reabsorption with consequent water attraction and insurgence of hypertension, which damages the endothelium integrity of vessels (Scott CL 2003).

Augmented endothelial permeability allows the passage of lipoproteins and platelet-derived growth factors (PDGF), which give rise to the proliferation of muscular smooth cells in the intima, which occludes vessel lumen and causes embolia, hypoxia, and consequent cellular death (Arthur H et al 2007).

In a sample of 31,543 participants of the Health Professionals' Follow-Up Study, based on a prospective cohort of 40- to 75-year-old men at baseline, with no prior hypertension history and complete baseline information on oral health, an incidence of 10,828 cases of hypertension over 20 years of follow-up was identified, with no significant association between incident hypertension and periodontal disease. In a study population of 182 adults, a multivariate analysis showed no association between severe periodontitis and hypertension history (OR = 0.99; 95% CI: 0.40-2.48).

Severe periodontitis was associated with high blood pressure, with an OR of 2.93 (95% CI: 1.25-6.84) after adjusting for age, gender, smoking, and binge drinking.

This association was stronger when restricted to those with hypertension or taking antihypertensive medications, suggesting that periodontitis may contribute to poor blood pressure control among older adults (Rivas-Tumanyan S et al 2012).

Regarding the biological mechanism of this relationship, a recent study evaluated endothelial function in patients with periodontitis.

Circulating levels of CRP and IL-6 were significantly higher in the periodontitis subjects with hypertension, than in the control group. Periodontal therapy seems to reduce serum concentrations of CRP and IL-6 (Higashi Y et al 2008).

mediators related to endothelial and cardio-circulatory dysfunctions.

A very recent work reported a real relationship between periodontitis and MetS, especially in women, while abdominal obesity was the largest contributory factor in both gender.

CHAPTER-7

OXIDATIVE STRESS: A COMMON LINK BETWEEN METABOLIC SYNDROME AND PERIODONTAL DISEASE

Oxidative stress is defined as a persistent imbalance between the production of highly reactive molecular species (e.g., reactive oxygen species [ROS], reactive nitrogen species [RNS]) and anti-oxidant defenses (Halliwell, 1991).

There is an increase in ROS in the pre-diabetic stage, likely due to obesity related elevations of FFA, and several studies have shown that reversal of the imbalance between ROS and anti-oxidants improves insulin resistance in mice and humans (Ceriello and Motz, 2004; Wright et al., 2006).

Periodontitis is a generally chronic disorder characterized by the breakdown of the tooth-supporting tissues and the impaired host inflammatory immune response. This condition is due fundamentally to an ecological imbalance between the normal microbial biofilm on teeth and the host tissues (Newman, 1974). There is increasing evidence linking periodontitis to systemic diseases (Kuo et al., 2008), such as diabetes (Herring and Shah, 2006),rheumatoid arthritis (Pischon et al., 2008b), and, especially, CVD (Ford et al., 2007; Paquette et al., 2007; Fardi and Papadimitriou, 2008)—hence the search for factors that may explain such relationships.

A potential factor which could increase insulin resistance is the production of oxidative stress enhancing ROS in affected periodontal tissues (Battino et al., 1999; Chapple and Matthews, 2007).

Insulin resistance plays a key role in the pathophysiology of MetS. Several inflammatory mediators are involved in the pathogenesis of insulin resistance, with TNF-α having

apparently the strongest effect (Tilg and Moschen,2008). The most important tissues involved in the pathogenesis of this disorder are muscle and adipose tissue.

When caloric intake exceeds energy expenditure, the resultant substrate-induced increase in citric acid cycle activity generates an excess of ROS (Maddux et al., 2001). Oxidative stress alters the intracellular signaling pathway, inducing insulin resistance (Evans et al., 2003).

Recently, a study with a murine model (Matsuzawa-Nagata et al., 2008) has shown that the pathways for ROS production and oxidative stress are up-regulated in both the liver and adipose tissue of mice fed a high-fat diet before the onset of insulin resistance.

Moreover, the increased ROS production was previous to the TNF-α and FFA elevation in the plasma and liver. In agreement with this hypothesis, insulin resistance is associated with reduced intracellular anti-oxidant defense in humans (Bruce et al., 2003), and anti-oxidants improve insulin sensitivity (Paolisso and Giugliano, 1996; Ceriello, 2000).

There is a spectrum of potential molecular and cellular damage derived from ROS production. Lipoprotein modification takes place in the absence (glycation) and presence (glycoxidation) of oxygen (Baynes and Thorpe, 2000), and these modifications can alter their structure and function (Jenkins et al., 2004). These modified lipoproteins are formed through a non-enzymatic process in which sugars bind to free amino groups of the lipoprotein(Njoroge and Monnier, 1989; Basta et al., 2004).

Lipid peroxidation is the formation of lipid peroxides via an enzymatic and/or a non-enzymatic mechanism. ROS resulting from hyperglycemia are thought to contribute to the initiation of lipid peroxidation (Cosentino et al., 1997). Once formed, lipid peroxides undergo a series of complex reactions, ultimately binding chemically to proteins. Thus, lipoxidation is the covalent binding of products of lipid

peroxidation reactions to proteins (Esterbauer et al., 1991, 1992; Spiteller, 1998; Jenkins et al., 2004).

Several studies have demonstrated a relationship between MetS and oxidative stress in humans. Thus, systemic oxidative stress is significantly higher in persons with MetS compared with non-obese normolipidemic individuals.

Some HDL-C subfractions possess significantly lower specific anti-oxidative activity in affected persons than their counterparts in control individuals, and this attenuated anti-oxidative activity of HDL-C subfractions correlates with systemic oxidative stress and insulin resistance (Hansel et al., 2004). In agreement with these results, persons suffering from MetS have poor anti-oxidant status and significantly increased oxidative stress (serum lipid peroxide level), compared with those without MetS (Sharma et al., 2005).

Moreover, obese adults with MetS have significantly higher plasma concentrations of oxidized-LDL-C, compared with obese adults without this condition (Van Guilder et al., 2006). By contrast, Sjogren et al. (2005) found no significant differences for plasma oxidized-LDL-C and urinary 8-iso-prostaglandin F2α (8-iso-PGF2α) between healthy and MetS men.

Advanced glycation end-products (AGE) are important markers for oxidative stress, and their endogenous secretory receptor (esRAGE) in plasma, as a soluble decoy receptor for

AGE, is significantly and inversely correlated with components of the MetS, including body mass index, blood pressure, triglyceride, glycated hemoglobin (HbA1c), and an insulin resistance index (Koyama et al., 2005).

As previously mentioned, oxidative stress is one of the main factors studied to explain the pathophysiological mechanisms of inflammatory conditions, such as MetS and periodontitis.

A recent and exhaustive review (Chapple and Matthews, 2007) has described the complex role of oxidative stress in relation to periodontal breakdown.

It seems that peripheral blood neutrophil hyperactivity in chronic and aggressive periodontitis exists as a constitutional element (Matthews et al., 2007a,b), rather than being entirely the result of peripheral priming by cytokines or plaque bacterial LPS.

In addition, there may be possible baseline hyperactivity, with low-level extracellular ROS release in the absence of any exogenous stimulus in persons with periodontitis (Gustafsson and Asman, 1996; Gustafsson et al., 1997; Fredriksson et al., 1998; Matthews et al., 2007b).

There is increasing evidence for compromised anti-oxidant capacity in periodontal tissues and fluids, independent of smoking, and increased AGE levels in persons with type 2 diabetes and in smokers, which are risk factors for periodontitis.

Such oxidation products can increase neutrophil adhesion, chemotaxis, and priming in hyper-reactive neutrophils, and might augment the damaging effects of the resultant oxidative stress (Brock et al., 2004; Palmer et al., 2005; Panjamurthy et al.,2005).

In addition to this, the up-regulation of pro-inflammatory transcription factors, such as NF-κB and activating protein-1, in inflamed periodontal tissues contributes to reduced glutathione depletion and ROS generation (Chapple, 1997; Janssen- Heininger et al., 2000).

It is important to emphasize the influence of periodontitis on serum and/or plasma oxidative markers in humans. Several studies have demonstrated an increase in products of oxidative damage in peripheral blood from persons with periodontitis compared with control individuals (Battino et al., 2001; Montebugnoli et al., 2004; Baltacioglu et al., 2008).

Moreover, it is evidence of a decreased anti-oxidant capacity in persons with periodontitis, evaluated by different assays (Chapple et al., 2002, 2007; Battino et al., 2003; Brock et al., 2004; Panjamurthy et al., 2005; Baltacioglu et al., 2006; Akalin et al., 2007; Konopka et al., 2007;Zilinskas et al., 2007).

Therefore, it might be argued that this increased pro-oxidative state and decreased anti-oxidant capacity in persons with periodontitis could facilitate the onset of a decrease in insulin sensitivity, which could be aggravated by a high fat diet in these persons.

This is in agreement with the previously mentioned report which demonstrated that an increase in ROS production precedes insulin resistance (Matsuzawa-Nagata et al., 2008).

Conversely, the presence of MetS or any of its components in a previously periodontally healthy person could facilitate a prooxidant state which would diminish anti-oxidant capacity of the periodontal tissues, and the response of these tissues to bacterial challenge could be impaired.

The presence of a high RAGE expression in periodontal tissues (Katz et al., 2005) is an important finding supporting the sensitivity of these tissues to products derived from oxidative damage.

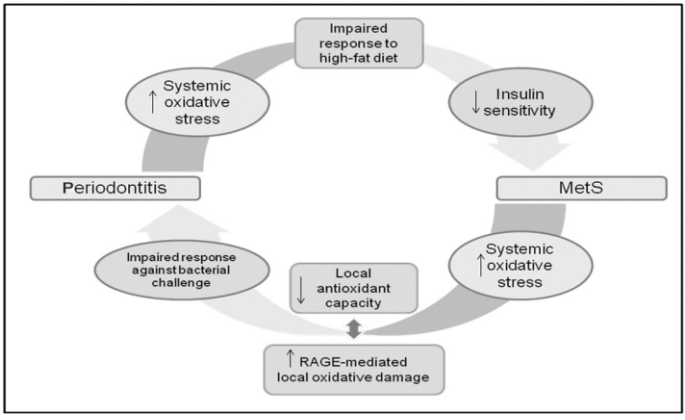
Hypothetic role of oxidative stress as a link between periodontitis and metabolic syndrome (MetS) promote apoptosis in osteoblasts (Alikhani et al., 2007a) and fibroblasts (Alikhani et al., 2007b), and this might have an influence on alveolar bone homeostasis and the progression of periodontitis.

Leptin and adiponectin appear as potential candidates to influence in a positive or negative manner, respectively, over the pro-oxidative state in periodontitis and MetS. Leptin has been demonstrated to have a predominantly pro-

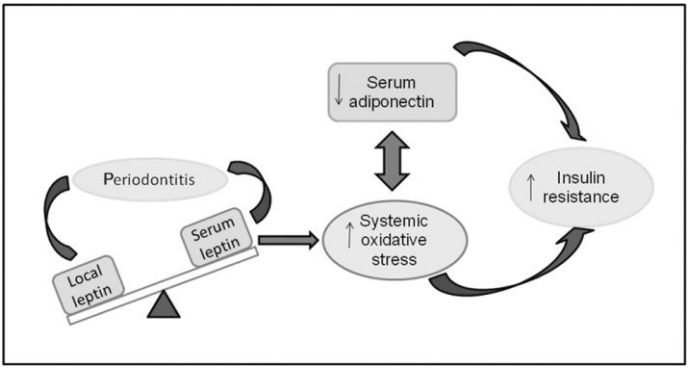
oxidative effect (Bouloumie et al., 1999; Maingrette and Renier, 2003; Suzuki et al., 2003; Beltowski et al., 2004).

The increased serum leptin levels existing in persons with periodontitis, possibly in an attempt to modulate the immune response, could be one of the factors that induces oxidative stress and accelerates the onset of insulin resistance.

This increased oxidative stress could facilitate a relative hypoadiponectinemia (Hattori et al., 2005; Soares et al., 2005; Katsuki et al., 2006), like that presenting in persons with periodontitis, which could also decrease the protection against oxidative damage, since this adipocytokine has been demonstrated to have a protective effect against oxidative stress (Nakanishi et al., 2005; Barazzoni et al., 2007.



Hypothetic role of oxidative stress as a link between periodontitis and metabolic syndrome (MetS). (P. Bullon et al, 2009)



Proposed roles of leptin and adiponectin as putative mediators in the oxidative imbalance enhancing periodontitis and insulin resistance. (P. Bullon et al, 2009)

CHAPTER: 8

LABORATORY INVESTIGATIONS OF METABOLIC SYNDROME

In the case of the WHO, abnormal values for blood pressure, urinary albumin excretion, and triacylglycerol and HDL-cholesterol concentrations will determine whether an insulin-resistant person has or does not have metabolic syndrome.

In the case of the IDF definition, even if a person displayed all of these abnormalities and had type 2 diabetes in addition, he or she would not have the metabolic syndrome if the Wiast circumference was not large enough.

The ATPIII version of the metabolic syndrome is the most democratic; there is no hierarchical relation between the 5 components, and any combination of 3 will do.

The lack on the part of the ATP III of assigning any priority to the 5 components of the metabolic may be a reflection of the panel's view that the cluster of abnormalities "probably has more than one cause".

It is difficult to disagree with the conclusion that the related abnormalities that make up all 3 versions of metabolic have more than one cause. For example, it is obvious there are many potential reasons for elevated blood pressures.

Glucose intolerance:

The prevalence of some degree of abnormal glucose tolerance or type 2 diabetes (or both)—one of the criteria in all 3 definitions of the metabolic syndrome—is the abnormality most closely related to insulin resistance.

Himsworth and Kerr challenged the conventional wisdom that "all cases of human diabetes could be explained by deficiency of insulin,"proposed that "a state of diabetes

might result from inefficient action of insulin as well as from a lack of insulin," and stated, "the diminished ability of the tissues to utilize glucose is referable either to a deficiency of insulin or to insensitivity to insulin, although it is possible that both factors may operate simultaneously."

It is now appreciated that insulin resistance is a common characteristic of patients with type 2 diabetes and that insulin resistance (or hyperinsulinemia as a surrogate estimate of insulin resistance) is a powerful and independent predictor of type 2 diabetes (Reaven GM et al 1993).

Finally, the greater the degree of insulin resistance, the higher the plasma glucose response to oral glucose in persons with normal oral glucose tolerance.

Thus, an enormous amount of evidence documents a very close relation between insulin resistance and abnormal elevations in plasma glucose concentrations.

Finally, it should be emphasized that nondiabetic persons with relatively minor degrees of glucose intolerance also have higher blood pressures and the dyslipidemic changes—high triacylglycerol and low HDL-cholesterol concentrations—that make up the remaining metabolic criteria of all 3 definitions of the metabolic syndrome.

Dyslipidemia:

There is a highly significant relation between insulin resistance, compensatory hyperinsulinemia, and hypertriglyceridemia.

It is now apparent that the link between insulin resistance or hyperinsulinemia and dyslipidemia is a much broader one, which is not limited to an increase in plasma triacylglycerol concentrations.

Thus, although the various definitions of metabolic syndrome have selected the combination of high plasma triacylglycerol and low HDL-cholesterol concentrations as

a diagnostic criterion, it is clear that these changes are also associated with a decrease in LDL particle size (small, dense LDL) and the postprandial accumulation of triacylglycerol-rich remnant lipoproteins.

Not only are all of these changes significantly associated with insulin resistance or hyperinsulinemia, but each one has also been shown to increase the risk of CVD.

Plasma triacylglycerol concentrations:

Implicit in these findings is the view that the major cause of elevated plasma triacylglycerol concentrations in nondiabetic persons is an increase in hepatic VLDL-triacylglycerol secretion rate, secondary to insulin resistance and the resultant hyperinsulinemia.

These data provide a quantitative estimate of the close relation between insulin resistance, compensatory hyperinsulinemia, hepatic VLDL triacylglycerol secretion, and plasma triacylglycerol concentrations in apparently healthy persons.

Relation between insulin resistance and plasma triacylglycerol concentrations

	Relation
Triacylglycerol 69–546 mg/dL2	IMGU 3 insulin concentration (r 0.74) 3 VLDL-triacylglycerol secretion rate (r 0.74) 3 triacylglycerol concentration (r 0.88)
33–174 mg/dL3	IMGU 3 insulin concentration (r 0.81)

	3 VLDL-triacylglycerol secretion rate (r 0.68) 3 triacylglycerol concentration (r 0.87)

IMGU, insulin-mediated glucose uptake, VLDL: Very low density lipoproteins

Postprandial lipemia:

The higher is the fasting triacylglycerol concentration, the greater will be the postprandial accumulation of triacylglycerol rich lipoproteins (ie, VLDL, chylomicron remnants, and VLDL remnants) in nondiabetic persons (Nestel PJ 1964)

Both the relation between fasting triacylglycerol concentration and postprandial lipemia and the daylong increases in triacylglycerol-rich

lipoproteins in nondiabetic persons are significantly correlated with the magnitudebof the insulin resistance and compensatory hyperinsulinemia.

Although the postprandial elevation of triacylglycerol-rich lipoproteins is related to the fasting triacylglycerol concentration, postprandial lipemia is also enhanced when insulin-resistant or hyperinsulinemic persons are matched by degree of fasting hypertriglyceridemia with persons from an insulin-sensitive population.

HDL cholesterol:

Increases in plasma VLDL-triacylglycerol concentration are usually associated with low HDL-cholesterol concentrations, and it appears that insulin resistance and compensatory hyperinsulinemia are independently associated with both of these changes.

Low HDL-cholesterol concentrations in insulin resistant or hyperinsulinemic persons are partly due to the transfer, which is catalyzed by cholesteryl ester transfer protein, of cholesterol from HDL to VLDL; the higher the VLDL pool size, the greater the transfer rate from HDL to VLDL and the lower the resulting HDL-cholesterol concentration.

The fractional catabolic rate of apoprotein A-I is increased in patients with primary hypertriglyceridemia, hypertension, and type 2 diabetes.

In type 2 diabetes, it has been shown that the greater the degree of hyperinsulinemia, the lower the HDL cholesterol concentration.

Evidence also exists that, in nondiabetic persons, the higher the fractional catabolic rate of apoprotein A-I, the lower the HDL-cholesterol concentration, and that these changes are associated with increases in plasma insulin concentrations LDL particle diameter.

Analysis of LDL particle size distribution has identified multiple distinct LDL subclasses, and it appears that LDL particles in most persons can be characterized by a predominance of larger LDL (diameter:255 Å; pattern A) or smaller LDL (diameter:255 Å; pattern B). Persons with pattern BLDL have higher plasma triacylglycerol and lower HDL-cholesterol concentrations than do persons with pattern A LDL.

Atherogenic lipoproteins and insulin resistance:

The evidence discussed above provides strong support for the conclusion that the lipoprotein abnormalities that are part of all 3 definitions of the metabolic syndrome are more likely to occur together and are significantly associated with insulin resistance and compensatory hyperinsulinemia.

However, not all persons with these abnormalities are insulin resistant. A high fasting plasma triacylglycerol concentration and hyperchylomicronemia can occur in

persons who have a primary defect in the catabolism of triacylglycerol-rich lipoproteins (ie, fat-induced lipemia).

Furthermore, not all insulin-resistant persons will develop the atherogenic lipoprotein profile associated with the defect in insulin action.

On the other hand, insulin resistance or hyperinsulinemia is the only physiologic abnormality that can lead to the clustering of abnormalities that includes the atherogenic lipoprotein profile discussed above, as well as increases in plasma glucose concentration and blood pressure.

Blood pressure:

The relation between insulin resistance, elevated blood pressure, and CVD is more complicated than that of any of the other components that make up the various definition of metabolic syndrome.

There is substantial evidence for the following 3 findings

Linking insulin resistance and hyperinsulinemia to essential hypertension.

First, patients with essential hypertension, as a group, are insulin resistant and hyperinsulinemic. Second, normotensive first-degree relatives of patients with essential hypertension are more insulin resistant and hyperinsulinemic than are matched control subjects without a family history of hypertension.

Third, hyperinsulinemia, as a surrogate estimate of insulin resistance, has been shown in population based studies to predict the eventual development of essential hypertension.

In contrast, probably no more than 50% of patients with essential hypertension are insulin resistant.

However, it is patients with essential hypertension who are insulin resistant or hyperinsulinemic who have the other components of the various definitions of metabolic syndrome and are therefore at greatest risk of CVD. For example, patients with essential hypertension and

electrocardiographic evidence of myocardial ischemia are insulin resistant, somewhat glucose intolerant, and hyperinsulinemic and have high triacylglycerol and low HDL-cholesterol concentrations compared with a normotensive control group or patients with essential hypertension whose electrocardiograms are entirely normal.

Direct evidence of the link between the dyslipidemia present in insulin-resistant or hyperinsulinemic patients with essential hypertension and CVD comes from the results of the Copenhagen Male Study, in which 2906 participants were divided into 3 groups according to their fasting plasma triacylglycerol and HDL-cholesterol concentrations.

Men whose plasma triacylglycerol and HDL-cholesterol concentrations were in the upper or lower third, respectively, of the whole population, were assigned to the high-triacylglycerol–low-HDL-cholesterol group.

At the other extreme, a low triacyl glycerol– high-HDL-cholesterol group was composed of those persons whose plasma triacylglycerol and HDL cholesterol concentrations were in the lower and upper thirds, respectively, of the study population for these 2 lipid measurements.

The intermediate group consisted of those participants whose lipid values did not qualify them for either of the 2 extreme groups. The results of this prospective study indicated that CVD risk was not increased in patients with hypertension in the absence of high triacylglycerol and low HDL-cholesterol concentrations, and the group at greatest risk was made up of those persons with high blood pressure and high triacylglycerol and low HDL-cholesterol concentrations.

In summary, insulin-resistant or hyperinsulinemic persons are more likely to develop essential hypertension, hypertension is a well-recognized CVD risk factor, and patients with essential hypertension and high triacylglycerol

and low HDL-cholesterolconcentrations are at greatest risk of CVD.

Insulin resistance and procoagulant and proinflammatory factors:

Although measures of procoagulant or proinflammatory factors have not been elevated to the status of diagnostic criteria, definitions of the metabolic, all comment on their relation with the cluster of abnormalities that make up the definition.

The association between insulin resistance and hyperinsulinemia, elevated concentrations of plasminogen activator inhibitor-1, and CVD has been known for some time. Concentrations of plasminogen activator inhibitor-1 in a group of apparently healthy persons was significantly correlated with degree of insulin resistance (as quantified by steady-state plasma glucose concentrations during the insulin suppression test), and fasting plasma insulin, triacylglycerol, and HDL cholesterol concentrations.

Thus, variations in concentrations of plasminogen activator inhibitor-1 cluster with insulin resistance or compensatory hyperinsulinemia, and the dyslipidemia characteristic of the defect in insulin action.

The proinflammatory factor currently attracting the most attention as indicating increased CVD risk is C-reactive protein, but there is a much longer history of a relation between an increase in white cell count and heart disease.

Indeed, data from the Women's Health Initiative Observational Study suggest that a high white cell count was comparable in magnitude to increases in concentrations of C-reactive protein as a predictor of CVD risk.

Evidence of a relation between white cell counts and insulin resistance or compensatory hyperinsulinemia was published several years ago (67); the evidence indicated that the higher the white cell count, the more insulin resistant person.

The relations described in this section provide evidence that the additional CVD risk factors considered to be present in patients diagnosed as having metabolic syndrome are significantly related to both insulin resistance and hyperinsulinemia, as well as to the other components of the metabolic syndrome.

Excess Adiposity, Insulin Resistance and Metabolic Syndrome:

Specifically, dyslipidemia (high triacylglycerol and low HDL-cholesterol concentrations), hyperglycemia, and hypertension are independent factors that directly increase the risk of CVD, whereas the relation between excess adiposity and CVD risk is different. For example, substantial numbers of overweight or obese persons do not have the abnormalities outlined above (Abbasi F et al 2002).

The components of the metabolic syndrome occur more commonly in overweight or obese persons, but this relation is not due to obesity, but rather to the fact that excess adiposity increases the likelihood that a person will be insulin resistant.

However, prospective studies exist that can serve as the basis for an operational definition. With the use of the magnitude of the insulin response to oral glucose as a surrogate maker of insulin resistance, 25% of an apparently healthy population with the highest insulin concentrations is at a significantly greater risk of CVD (Zavaron.I et al 1999).

According to the results of 2 prospective studies in which the insulin suppression test was used to quantify IGMU at baseline, the third of the population that was the most insulin resistant (ie, those with the highest steady-state plasma glucose concentrations) was at significantly greater risk of CVD than was the population third that was the most insulin sensitive (ie, those with the lowest steady-state plasma glucose concentrations).

Thus, for the purposes of this discussion, the third of the population with the highest steady-state plasma glucose concentrations will be operationally defined as insulin-resistant, and the third with the lowest steady-state plasma glucose concentrations will be defined as insulin-sensitive.

Visceral Obesity:

Evidence has shown that measurements of BMI and WC are highly correlated, that they are associated with a specific measure of IMGU to an identical degree, and that not all overweight or obese persons are insulin resistant.

This is because discrepant opinion of the importance of abdominal obesity in the genesis of insulin resistance and its consequences is the failure to take into consideration the importance of visceral obesity.

Relation between adiposity, insulin resistance, and risk of cardiovascular disease:

Rates of IMGU vary 600% in apparently healthy persons, and, because the distribution of these values is continuous (Yeni-Komshian et al 2000), there is no objective way to classify a person as insulin-resistant.

However, prospective studies exist that can serve as the basis for an operational definition. With the use of the magnitude of the insulin response to oral glucose as a surrogate maker of insulin resistance, 25% of an apparently healthy population with the highest insulin concentrations is at a significantly greater risk of CVD (Zavaron I et al 1999).

LABORATORY VALUES OF PATIENT WITH PERIODONTITIS AND METABOLIC SYNDROME:

Measured test	Value	Range
Fasting blood sugar	246mg/dl(H)	65-110mg/dl
HbA1c	11.3%(H)	4-6%(non-diabetic) Less than 7 for diabetic
Lipid profile Total serum cholesterol High Density Lipoprotien Cholesterol/HDL ratio Triglycerides	 223mg/dl 29mg/dl(L) 7.7(H) 141mg/dl	 150-200mg/dl More than 40mg/dl for men 3.8 50-150mg/dl
Blood pressure	140/90mm Hg	130/85mm Hg
Body Mass Index	27.68kg/m^2	27.65kg/m^2
Waistline	94cm(H)	90cm

CHAPTER-9

MANAGEMENT OF METABOLIC SYNDROME AND PERIODONTITIS

The treatment of metabolic syndrome patients with periodontitis can be divided into two categories

1) Medical management.
2) Periodontal management.

MetS is a state of chronic low grade inflammation with the profound systemic effects.

Clinical identification and management of patients with the MetS are important to begin efforts to adequately implement the treatments to reduce their risk of subsequent diseases.

Effective preventive approaches include lifestyle changes, primarily weight loss, diet, and exercise, and the treatment comprises the appropriate use of pharmacological agents to reduce the specific risk factors.

The clinical management of MetS is difficult because there is no recognized method to prevent or improve the whole syndrome, the background of which is essentially insulin resistance (G. M. Reaven 1988).

Thus, most physicians treat each component of MetS separately, laying a particular emphasis on those components that are easily amenable to the drug treatment.

Multidisciplinary approach to the MetS[8]

A: assessment

Calculate Framingham risk score: high risk (10-year risk ≥20%), moderately high risk (10-year risk 10% to 20%), or lower to moderate risk (10-year risk ≤10%). Make diagnosis of MetS using the diagnostic criteria.

A: aspirin

High risk: aspirin definitely beneficial.

High-intermediate risk (10–20%): aspirin likely to be beneficial.

Low-intermediate risk (6–10%): "individual clinical judgment", depending on sex and risk of bleeding.

Low risk (<6%): Risk of haemorrhage outweighs the benefits.

B: BP control

Initiate treatment: categorical hypertension (BP ≥ 140/≥90mmHg).

Patients with established diabetes (≥130/≥80mmHg).

ACEIs/ARBs first line agent may reduce incident diabetes mellitus.

Beta-blockers and thiazides may have an adverse effect on impaired glucose tolerance but outweighed by the benefits of reaching BP goal and lowering the risk of CVD events.

C: cholesterol

First target: LDL

Second target: non-HDL

Third target: HDL

Fourth target: CRP

Statin to achieve LDL-C <100mg/dL in high-risk, <130mg/dL in intermediate-risk, and <160mg/dL in low risk patients.

Statin intensification, consider niacin and/or fibrates once statin maximized. Consider fibrates, especially for those with combined hypertriglyceridemia/low HDL-C.

Consider further reduction in LDL-C with statin therapy to mitigate a risk of low HDL-C, consider niacin.

Statin therapy for those with high sensitivity CRP (hsCRP) ≥3mg/dL.

D: Diabetes prevention/diet

Intensive lifestyle modification is the most important therapy.

Weight reduction of 5–10% of preintervention weight over a period of four to six months.

Sodium intake of <65–100mmol/day with a goal of 90–120mmol of potassium per day.

Mediterranean diet: high consumption of fruits, vegetables, legumes, and grains, moderate alcohol intake, a moderate-to-low consumption of dairy products and meats/meat products, and a high monounsaturated- to-saturated fat ratio.

DASH diet: rich in fruits, vegetables, and low-fat dairy products, and low in saturated and total fat intake.

Consider low glycemic index food, complex unrefined carbohydrates, viscous soluble fibres, protein intake of 10–35% of total calorie intake and 25% to 35% of calories as total fat.

Metformin is second line in delaying the onset of T2DM.

Thiazolidinediones (Pioglitazones) and alpha-glucosidase inhibitors (Acarbose) have shown benefit in smaller studies and are therefore third line.

E: exercise

Daily moderate intensity activity of minimum 30 minutes for most days of the week. Recommend use of pedometer with goal >10,000 steps/day.

Formulated Treatment Plan For Metabolic Syndrome and Periodontal Disease Patients [51]:

Full mouth disinfection of the patient is an important perspective to prevent the severity of both metabolic syndrome and periodontitis.

Phase 1 Therapy (Etiotropic Phase):

1: Referral to medical physician for management of diabetes, hypertension and hypercholesterolemia. Hypertensive patients on calcium channel blockers which can cause gingival enlargement are substitutedwith other drugs after consultation of physician.

2: Thorough scaling and root planning , full mouth disinfection under local anaesthesia.

3: Patient adviced chlorohexidine mouthwash 0.12% 1:1 dilution twice daily for fifteen days.

3: Patient advised unifloss for tight contacts and interdental brush for open contacts.

5: Patient education and motivation

6: Diet councelling.

7: Advise on stress management.

Phase 2 Therapy (Surgical Phase):

1: Endodontic treatment if required carried out first.

2: Extraction of teeth with poor prognosis and grade III mobility.

3: If diabetes, hypertension are controlled then open root surface debridement (flap surgery) and alveolar bone grafting if osseous defects are present.

Phase 3 Therapy (Restorative Phase):

1: Patient advised fixed or removable dentures in edentulous spaces.

2: Restoration for carious teeth.

Phase 4 Therapy (Maintainance Phase):

1: Revaluation of fasting blood sugar, glycated heamoglobin, hypertension and lipid profile in three months time following non surgical therapy.

2: Regular monitoring of periodontal condition and supportive therapy.

As part of the temporomandibular joint structure, the mandibular condyle is considered to play a key role in the stability of long-term treatment results after orthodontic and orthognathic treatments. Mandibular condyle plays pivotal role in the development of oro-facial complex, since it provides endochondral bone growth to function as a regional adaptive growth site and is known to adapt to different functional factors. Therefore, it has received special attention in orthodontics. On the contrary, impaired growth of the condyle contributes to the development of mandibular asymmetries and retrognathia, which are corrected in the orthodontic therapy in juveniles to improve functional relationship of the jaws. While cartilage of the mandibular condyle is often referred to as secondary, its main type is called primary cartilage, considered as a remnant of the cartilaginous skeleton, bulk of which forms bony skeleton.
This book aims to provide a broad perspective regarding the development, regulating factors, growth relativity hypothesis for condylar growth and current condylar growth concepts as well as clinical relevance in contemporary orthodontics.

Introduction

An understanding of the biological principles related to the development, growth and adaptation of the structures composing the craniofacial complex is essential for attaining competency within the field of orthodontics. Growth of the craniofacial skeleton largely influences occlusal relationships, jaw relationships, and orofacial functions.[1] In the growth of the craniofacial skeleton, cartilaginous tissues, including those of the sphenooccipital synchondrosis in the cranial base, the nasal septal cartilage in the nasomaxillary complex and the condylar cartilage in the mandible, plays important role as major growth sites for the respective anatomical components.[2,3] As part of the temporomandibular joint structure, the mandibular condyle is considered to play a key role in the stability of long-term treatment results after orthodontic and orthognathic treatments.

Mandibular condyle plays pivotal role in the development of oro-facial complex, since it provides endochondral bone growth to function as a regional adaptive growth site and is known to adapt to different functional factors. Therefore, it has received special attention in orthodontics. On the contrary, impaired growth of the condyle contributes to the development of mandibular asymmetries and retrognathia, which are corrected in the orthodontic therapy in juveniles to improve functional relationship of the jaws. While cartilage of the mandibular condyle is often referred to as secondary, its main type is called primary cartilage, considered as a remnant of the cartilaginous skeleton, bulk of which forms bony skeleton.[4]

FOR AUTHOR USE ONLY

During mandibular growth, the condyle undergoes endochondral ossification and the condylar cartilage acts as a template for bone growth.[5]

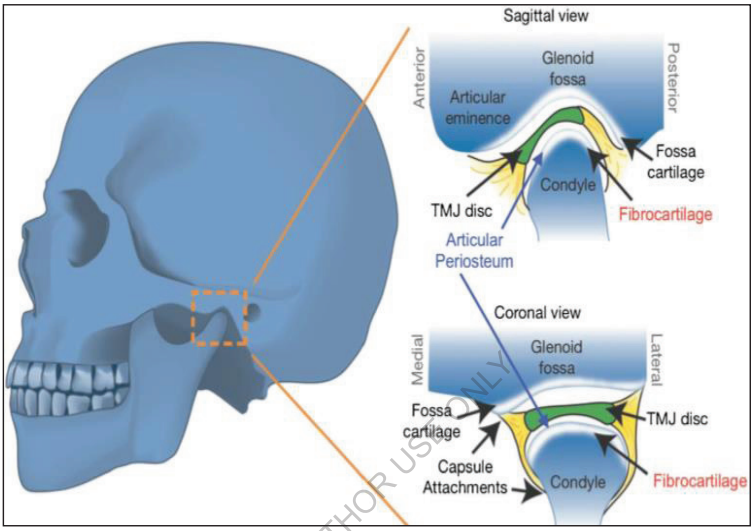
The condylar process grows in a wide range of directions from anterosuperior to posterior, resulting in highly diverse mandibular growth and morphology. Condylar growth direction is closely related to mandibular displacement (transposition) direction and vertical jaw deviations (i.e., high or low angle).[6] Only a single cartilage, the mandibular condylar cartilage exists in the mandible throughout life and plays role in articulating function and growth. Therefore, the condylar cartilage is an “all-in-one type tissue”.[7]

This book aims to provide a broad perspective regarding the development, regulating factors, growth relativity hypothesis for condylar growth and current condylar growth concepts as well as clinical relevance in contemporary orthodontics.

ANATOMY AND HISTOLOGY OF CONDYLAR CARTILAGE

ANATOMY

The area where the mandible articulates with the temporal bone of the cranium, is called the TMJ, is one of the most complex joints in the body as shown in Figure-1.



FOR AUTHOR USE ONLY

Fig 1. The TMJ is shown in the sagittal and coronal (frontal) view. (Taken from Stocum D, Roberts W. Part I: Development and Physiology of the Temporomandibular Joint. Current Osteoporosis Reports. 2018;16(4):360-368.)

TMJ is divided into

1. Cranial component
2. Mandibular component

The condyle is the portion of the mandible that articulates at the base of the cranium with the squamous portion of the temporal bone around which movement occurs. From the anterior view, it has medial and lateral projections, called poles as shown in Figure-2. The medial pole is generally more prominent than the lateral pole. From above, a line drawn through the centers of the poles of the condyle will usually extend medially and posteriorly toward the anterior border of foramen magnum as shown in Figure-3.

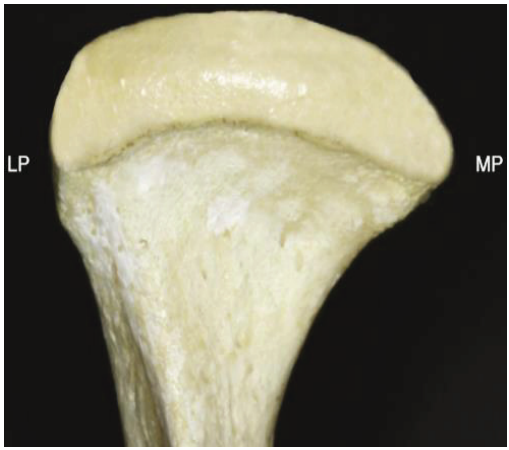


Fig 2. Condyle (Anterior view).The medial pole(MP) is more prominent than the lateral pole(LP). (Taken from Okeson. J. Management of temporomandibular disorders and occlusion. 7th ed. St Louis, Missouri Elsevier Mosby;2013:p.3-10.)

FOR AUTHOR USE ONLY

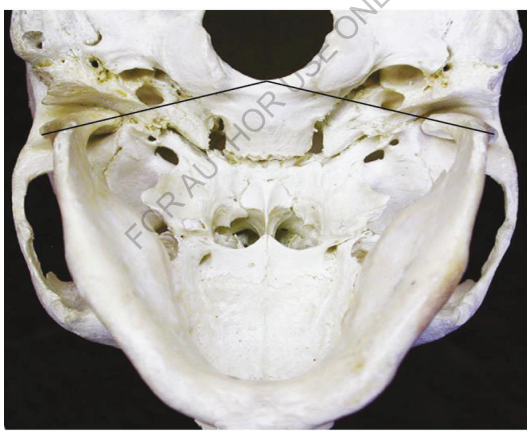

Fig 3. Inferior view of surface of the cranium and mandible. (Taken from Okeson. J. Management of temporomandibular disorders and occlusion. 7th ed. St Louis, Missouri Elsevier Mosby;2013:p.3-10.)

The total mediolateral length of the condyle is between 18 and 23 mm and the anteroposterior width is between 8 and 10 mm. The actual articulating surface of the condyle extends both anteriorly and posteriorly to the most superior aspect of condyle as shown in Figure-4 and 5. The posterior articulating surface is greater than the anterior surface. The articulating surface of the condyle is quite convex anteroposteriorly and only slightly convex mediolaterally.[8]

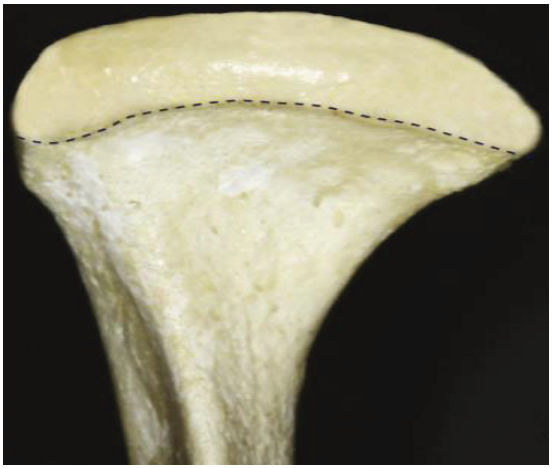

Fig 4. Condyle. (Anterior view). A dotted line marks the border of articular surface. (Taken from Okeson. J. Management of temporomandibular disorders and occlusion. 7th ed. St Louis, Missouri Elsevier Mosby;2013:p.3-10.)

FOR AUTHOR USE ONLY

Fig 5. Condyle (Posterior view). A dotted line marks the border of articular surface. (Taken from Okeson. J. Management of temporomandibular disorders and occlusion. 7th ed. St Louis, Missouri Elsevier Mosby;2013:p.3-10.)

HISTOLOGY

The mandibular condyle is covered by a zonal cartilage layer from the articular surface to the underlying bone, which serves to absorb shock and contributes to bone remodelling. Mature condylar cartilage of the mandible consists of four zones:

(1) Articular surface of fibrous tissue facing the disc expressing collagen I

(2) Proliferative cells in the prechondroblastic zone expressing collagen I

(3) Chondroblastic zone expressing collagen II, the proteoglycans aggrecan, decorin, chondroitin sulfate PG, and keratin sulfate PG.

(4) Hypertrophic zone adjacent to bone expressing collagen X as shown in Figure-6.

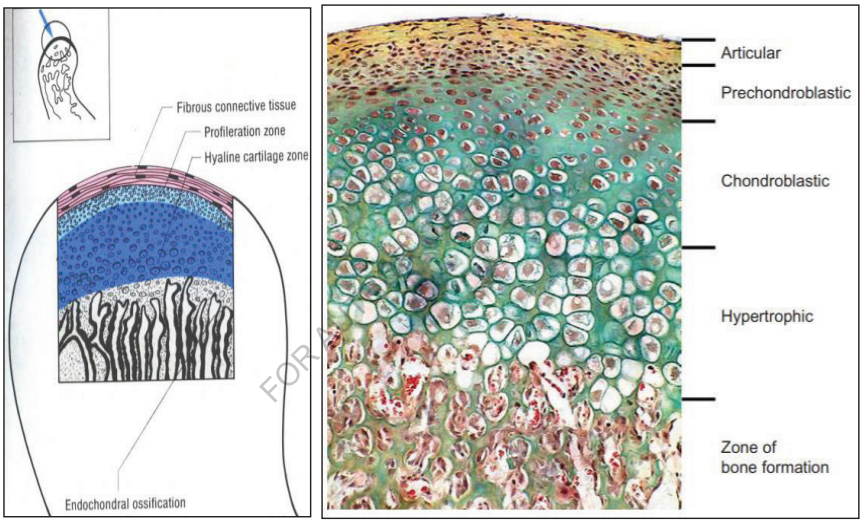

Fig 6. A histologic section of a healthy mandibular condyle showing the four zones: articular zone, proliferative zone, fibrocartilaginous zone, and the calcified cartilage zone. (Taken from Hinton R. Genes that regulate morphogenesis and growth of the temporomandibular joint: A review. Dev Dynam 2014;243(7):864-874.)

The most superficial layer is called the articular zone. It is found adjacent to the joint cavity and forms the outermost functional surface. This layer is made of dense fibrous connective tissue. Collagen fibers are oriented parallel to the cartilage surface but angled together to form a sheet-like structure.[9] The fibers are tightly packed and able to withstand the forces of movement. The articular fibrous zone is comprised of

fibroblast-like cells which have a flat shape and endoplasmic reticulum surrounded by dense cytoplasm.[10]

The second zone is called the proliferative zone and is mainly cellular. It is in this area that undifferentiated mesenchymal tissue is found. This tissue is responsible for the proliferation of articular cartilage in response to the functional demands placed on the articular surfaces during loading. Essentially, it serves as a separating barrier between the fibrocartilaginous fibrous zone and the hyaline-like mature and hypertrophic zones. Below the cartilage is the mandibular bone, with cancellous bone covered by a layer of compact cortical plate.[11] The proliferative zone indeed plays an important role as a cell reservoir, which has mesenchymal cells distributed heterogeneously as chondrocyte precursors for the underlying zones. Thus, it is likely that these mesenchymal cells partly contribute to the changes in the thickness and shape of mandibular condylar cartilage in adaptation.

In third zone is the collagen fibrils are arranged in bundles in a crossing pattern, although some of the collagen is seen in a radial orientation. The fibrocartilage appears in a random orientation, providing a three dimensional network that offers resistance against compressive and lateral forces.

FOR AUTHOR USE ONLY

The fourth and deepest zone is made up of chondrocytes and chondroblasts distributed throughout the articular cartilage. In this zone the chondrocytes become hypertrophic, die, and have their cytoplasm evacuated, forming bone cells from within the medullary cavity. The surface of the extracellular matrix scaffolding provides an active site for remodelling activity during endosteal bone growth, as it does elsewhere in the body.[12]

These various zones do not have linear columns of daughter cells. This is a notable histologic difference between primary and secondary types of growth cartilage. The nonlinear arrangement of the daughter cells in the condylar cartilage thus does not reflect the direction in which the condyle is growing. It also means that the cap of condylar cartilage has multidirectional proliferative capacity. This is one of the most significant developmental features of the condyle.

DEVELOPMENT OF SECONDARY CARTILAGE

The primary and secondary cartilages have different embryonic origins. The primary cartilage is different from most of the articular cartilages which are also primary, while the secondary cartilages appear later during the embryonic development, independent of the appearance of chondro-skeleton. Apart from constituting the mandibular condyle, secondary cartilage also occurs in the sutures of maxilla, mandibular symphysis and angular as well as coronoid processes. The two types of cartilages show differences in histological organization and in the pattern of cell proliferation.[12] By contrast, the secondary cartilage only secondarily follows these overall stimuli after additional modulation by local growth factors.[13] By approximately 10-12 weeks gestation, secondary cartilage appears.

As the cartilage comprising the mandibular condyle arises "secondarily" within a skeletogenic membrane and apart from the primary embryonic cartilaginous anlagen, it is referred to as a secondary cartilage as shown in Figure-7.

FOR AUTHOR USE ONLY

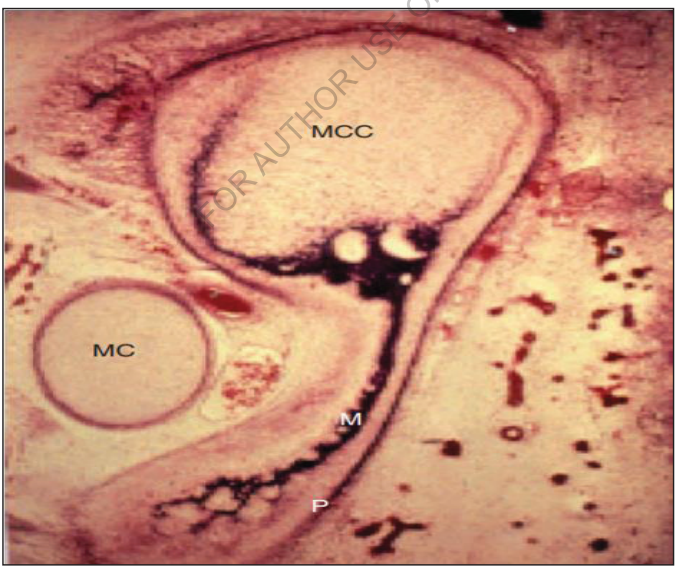

Fig 7. Frontal histologic section of a human foetus (approximately 8 weeks gestation). The bone comprising the body and ramus of the mandible (M) originates in membrane lateral to Meckel's cartilage (MC). The periosteal membrane enveloping the mandible gives rise secondarily to the mandibular condylar cartilage (MCC). (Taken from Graber LW,Vanarsdall RL & Vig KWL. Orthodontics: Current Principles and Techniques. 5th ed. Elsevier Health Sciences;2011:p.229-233.)

There are some important reasons to define condylar cartilage as secondary cartilage:

(1) Being late in ontogenetic development, the new cartilage develops within a mesenchymal blastema. Primary cartilages are covered by a thin perichondrium. Secondary cartilage is covered by a fully developed mesenchymal tissue layer. The mesenchymal covering of the condyle is responsible for a fundamental characteristic of the condylar cartilage. There are mesenchymal cells first and these cells differentiate into cartilage only as a secondary event.[12]

(2) The term 'secondary cartilage' may also apply to the characteristic response of the condyle during growth. Primary epiphyseal cartilage reacts during development, primarily to systemic growth stimuli such as hormones. In contrast, condylar cartilage only secondarily follows these overall stimuli after additional modulation by local growth factors.[13]

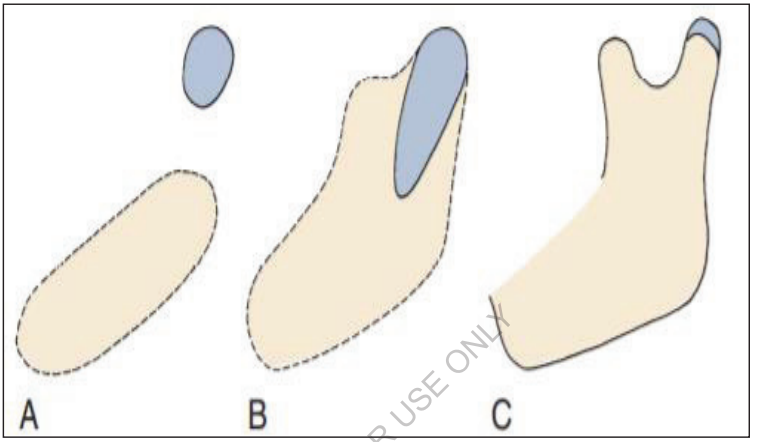
(3) In pre-natal development, most other synovial joints have already been formed before the temporomandibular joint.[14] The delayed occurrence of condylar cartilage was confirmed by immunolocalization of types II and X collagen in the fetal mouse mandible, where the immunoreactions were not positive until day 15 of pregnancy. The new articulation between the temporal bone and the mandible is therefore indicated as secondary, in contrast to primary joints formed earlier.

FOR AUTHOR USE ONLY

(4) Subsequent to all other true primary cartilages that form within the mesenchymal blastema of what will be the future mandible, new cartilage formation begins as a secondary event in 4 regions: the condylar process, the coronoid process, the symphysis, and the gonial area. The latter three will have disappeared around birth. Condylar secondary cartilage, remains for the rest of our lives. Probably due to articular functioning, cartilage is induced and maintained within the membranous components of the condylar process of the mandible.

Secondary cartilage is a unique type of skeletal tissue that has the characteristics of both intramembranous bone and certain histologic and functional features of hyaline growth cartilage. Secondary cartilage is formed in areas of precocious stresses and strains within intramembranous bones, as well as in areas of rapid development and growth of bone.[15] The secondary cartilage composing both the condylar and the temporal portion of the TMJ can be divided into two general layers: an articular tissue layer and a subarticular growth layer. Each of these layers is present in the neonate and remains in the condyle through maturity.[16] However, in the adults, the remnant condylar cartilage serves more ‘articular’ function than ‘growth’ function.[17]

The condylar cartilage appears at 12 weeks of development and rapidly forms a cone-shaped or carrot-shaped mass that occupies most of the developing ramus. This mass of cartilage is converted quickly to bone by endochondral ossification, so that at 20 weeks of development only a thin layer of cartilage remains in the condylar head as shown in Figure-8.



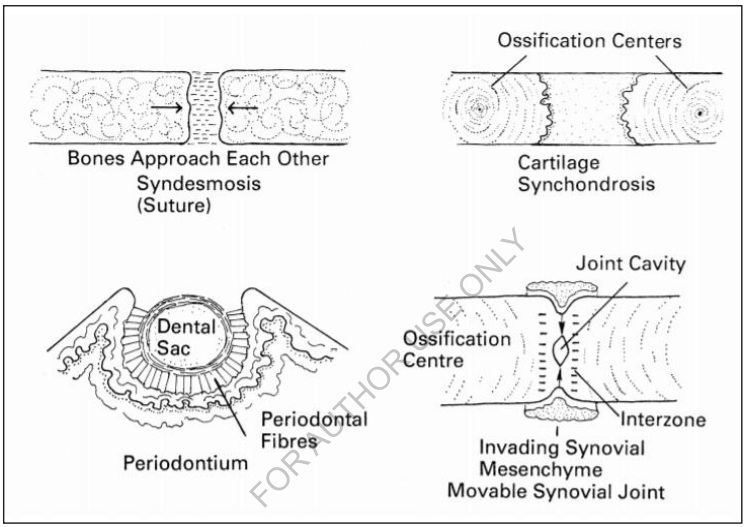
FOR AUTHOR USE ONLY

Fig 8. The condylar cartilage (blue) develops initially as a separate area of condensation from that of the body of the mandible and only later is incorporated within. (A) Separate areas of mesenchymal condensation at 8 weeks. (B) Fusion of the cartilage with the mandibular body at 4 months. (C) Situation at birth (Taken from Proffit WR, Fields Jr HW. Later stages of development. In: Proffit WR. Contemporary Orthodontics. 5th ed. St Louis, MO: Mosby;2000:p.87-104.)

This remnant of cartilage persists until the end of the second decade of life, providing a mechanism for growth of the mandible, in the same way as the epiphyseal cartilage does in the limbs.[18]

PRENATAL CONDYLAR GROWTH

The embryonic development of the temporomandibular joint differs considerably from that of other synovial joints, reflecting its complicated evolutionary history. Most synovial joints complete the development of their initial cavity by the 7th week post conception, but the temporomandibular joint does not start to appear until this time. Whereas limb joints develop directly into their adult form by cavity formation within the single blastema from which both adjoining endochondral bones develop as shown in Figure-9.



FOR AUTHORISE ONLY

Fig 9. Embryonic origins of various types of joints. (Taken from Sperber G. Craniofacial development. Hamilton, Ont.: B.C. Decker; 2001:p.126-142.)

The temporomandibular joint develops from initially widely separated temporal and condylar blastemata that grow towards each other.

The dorsal half of the arch gives rise to the maxillary process and the ventral half to the mandibular process. Within the mandibular process, Meckel's cartilage develops from the 8th to 16th weeks as shown in Figure-10.

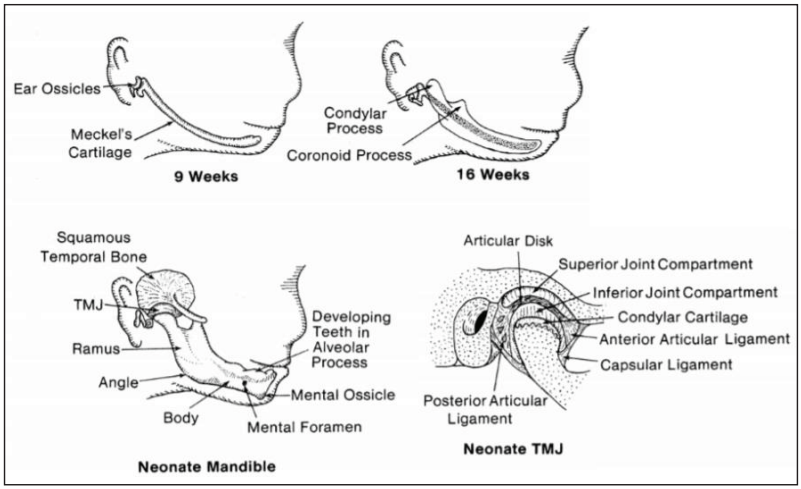


Fig 10. Development of the mandible and the temporomandibular joint. (Taken from Sperber G. Craniofacial development. Hamilton, Ont.: B.C. Decker; 2001:p.126-142.)

The temporal blastema arises from the otic capsule, a component of the basicranium that forms the petrous temporal bone. The term 'secondary cartilage' may also apply to the characteristic response of the condyle during growth.

The mandibular condyle in the fetal and newborn period is an articular cartilage, as well as an active skeletal growth center for the mandible, in the same way as the growth plates are the skeletal growth center for the long bones of the extremities. Most synovial joints complete the development of their initial cavity by the 7th week post conception, but the temporomandibular joint does not start to appear until this time. The embryonic origin of the TMJ involves neural crest mesenchyme migrating ventrally to form the first (mandibular) pharyngeal arch.[19]

The human TMJ develops in three stages between the 7th and 20th week

a) The glenoid fossa of the temporal bone
b) The condylar process of the mandibular ramus
c) The articular disc

The first phase (7th–8th week) is the approximation of the condylar process to the developing concavity of the glenoid fossa at the base of the temporal bone.

The second phase (9th–11th week) encompasses the coordinated development of the condyle and fossa, the articular disc, joint capsule, and joint cavities.

FOR AUTHOR USE ONLY

Endochondral ossification of the condylar process begins in the 17th week and after the 20th week the secondary cartilage is almost entirely ossified. The articular disc and joint capsule develop between the articular fossa and the condylar process. The disc forms in a biconcave shape and separates the joint cavity into two spaces, an upper space between the disc and the glenoid fossa, and a lower space between the disc and the condyle.

By the 20th week, the articular disc has differentiated into periosteal articular surface with underlying fibrocartilage.

This more complex process is consistent with the TMJ being a secondary joint with a periosteal articular surface that has regenerative potential.[20] Neural crest mesenchyme migrates during the fourth week of embryonic development to form the first branchial (mandibular) arches surrounding the prospective stomodeal region. During this time, a blastema forming the condylar secondary cartilage (CSC) develops beneath the periosteum from the ramal surface of the developing mandibular body and the development of the mandibular condyle is shown in Figure-11 [a,b]. The secondary cartilage blastema that forms the ramus and condyle arises at around 6 weeks in utero, from the medial surface of the intramembranous bone of the primordial mandibular body as shown in Figure-11a. The blastema originates in the subperiosteal space from osteogenic perivascular cells, so the secondary cartilage is covered with periosteum (blue outline) throughout its development. At about 20 weeks, the carrot-shaped condyle is formed (arrow in Figure-11b) via secondary cartilage that is mineralized to form the endochondral bone that composes a substantial portion of the subcondylar ramus (Figure-11c). The periosteal articular surface of the mandibular condyle is composed of the fibrous and cambium layers of the periosteum with an underlying cushion of fibrocartilage.[21] The buds for the deciduous molars are formed at the same time as the condyle (Figure-11b).

FOR AUTHOR USE ONLY

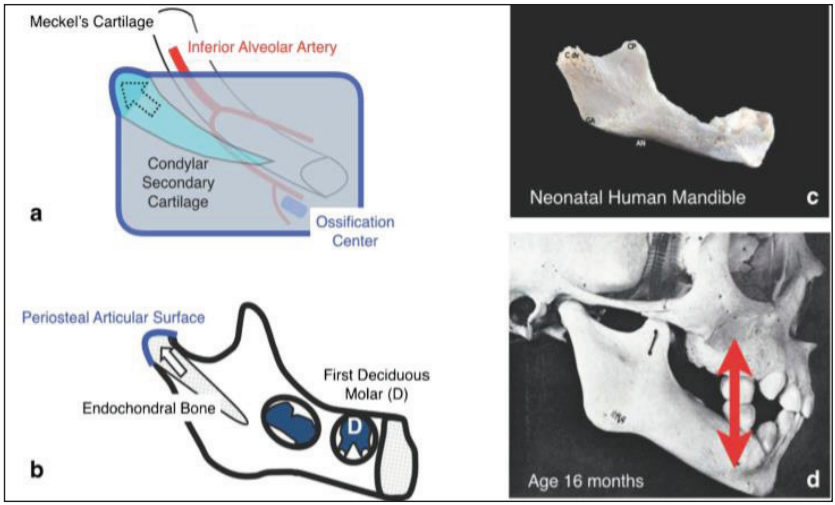

Fig 11. Biomechanics of mandibular development is illustrated for the right side: **a)** At 6–8 weeks in utero, bone formation begins at the ossification center and grows into a plate of bone (gray) surrounded by a periosteum (blue line). The condylar secondary cartilage emerges as a subperiosteal blastema from the lingual surface. **b)** From 8–20 weeks, the condyle grows in a superior and inferior direction. The condyle has a periosteal articular surface (blue line) with an underlying fibrocartilage layer that forms endochondral bone. The first deciduous molar (d) is forming at the same time. **c)** Neonatal human mandible shows the following skeletal landmarks: osseous portion of the condylar process (Cdr), gonial angle (GA), antegonial notch (AN), and corinoid process (CP). **d)** At ~16 months of age, the first deciduous molars (Ds) occlude bilaterally, resulting in heavy loads (red double-headed arrow) being equally distributed to the mandible and the cranium. (Taken from Stocum D, Roberts W. Part I: Development and Physiology of the Temporomandibular Joint. Current Osteoporosis Reports 2018;16(4):360-368.)

FOR AUTHOR USE ONLY

In contrast to other synovial joints, fibrous cartilage (rather than hyaline cartilage) forms on the articular facets of the temporal mandibular fossa and mandibular condyle. In the later site, the underlying secondary cartilage acts as a growth center.

POSTNATAL CONDYLAR GROWTH

Growth of the mandible was thought to occur principally by growth at condyle. Grow th of the condyle during the postnatal period is accompanied by a significant thickness, increase in the fibrous zone and an obvious thickness decrease in the hypertrophic zone, with an overall decrease in the cartilage thickness.[22] The traditional concept of mandibular growth views the condyle as a primary growth centre, which under the control of intrinsic factors not only governs the over-all growth of the mandible but also displaces the mandible downward and forward, thereby regulating the anteroposterior relationship of the mandible to the maxilla.

Superior and posterior growth of condyle presses against the glenoid fossa providing an anterior thrust to displace the lower jaw forward (similar to growth of maxilla). The concept of posterior growth and anterior displacement leads to primary displace ment. Charles (1925) concluded that the mandible growth is solely controlled by the growth that takes place at the top of the condyle.[23]

According to Moss (1969), who has expressed that the origin, growth and maintenance of the skeleton depend almost exclusively upon the functional matrix, to those tissues, organs, and functioning spaces related to any given skeletal element. Applying the hypothesis to the mandible, Moss failed to credit the condyle with any inherent growth and maintains that mandibular growth occurs as a secondary or adaptive response to the functional behaviour of the oral cavity and related orofacial musculature.[24]

FOR AUTHOR USE ONLY

The characteristics of cartilage make it a most appropriate tissue for performing two very important functions in the body.

1) The capacity of cartilage to produce a strong but flexible provisional supportive frame-work at a relatively high rate of growth fulfils a crucial function during embryonal and postnatal growth.

2) The chemical and physical properties of the matrix components give cartilage RESILIENCE, a property which is well suited to cushion compressive forces in loaded articular joints.

Mandibular condylar cartilage fulfils both functions, though for the greater part, diachronously. These functions influence the development and determine the ultimate shape and composition of the mandibular condyle. The relative intensity of expressions of the two functions during development was shown in Figure-12.

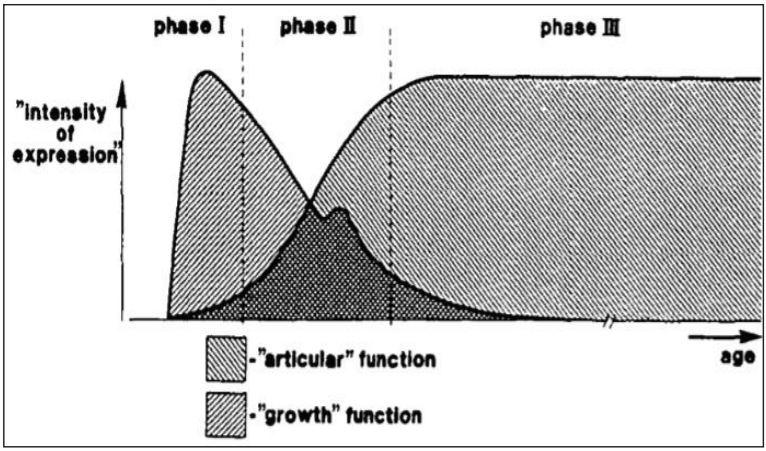

Fig 12. Graphic representation of the function of mandibular condylar cartilage during development. (Taken from Copray JC, Dibbets JM, Kantomaa T. The role of condylar cartilage in the development of the temporomandibular joint. Angle Orthod 1988;58(4):369-380.)

Each of these three phases reflects the changing functions of the mandibular condyle during development.

PHASE I- During phase I, the embryonal and the early postnatal stages, the mandibular condylar cartilage functions mainly as a growth cartilage. Although some intrauterine mandibular movements with functional activity in the TMJ have been observed, the articular function of the condylar cartilage still seems subordinate.

PHASE II- In phase II, the functional activity increases, causing the mandibular condylar cartilage to function more as an articular cartilage. Increase of the articular functioning is accompanied by a decrease of the growth activity, despite the hormonally induced growth spurt occurring during this stage. It starts before birth and runs until about 20 years of age, with growth activity continuing until approximately age 25.

PHASE III- In phase III, the orofacial muscular structure and activity reach their relatively stable adult stage and gradually the condylar cartilage functions almost entirely as an articular cartilage. The growth activity diminishes further and some maintenance turn over activity might be considered as the last remnant of the “growth” function.[17]

The secondary cartilage of the condyle is not the genetic pacemaker for the growth of the mandible. Its real contribution is to provide regional adaptive growth (i.e., growth

FOR AUTHOR USE ONLY

that is secondarily responsive to a variety of circumstantial conditions) thus giving yet another meaning for the term "secondary." The condylar cartilage is thus phylogenetically and ontogenetically unique and differs in histologic organization from most other growth cartilages involved in endochondral bone formation.

Thus, the condyle is not a "primary" center of growth, but rather

(1) Secondary in evolution;

(2) Secondary in embryonic origin;

(3) and secondary in adaptive responses to changing developmental conditions (regional adaptive growth) .

The post-natal growth of the mandible in terms of the changes taking place in different regions.

The Condylar neck

The lingual and buccal sides of the neck characteristically have resorptive surfaces as shown in Figure-13.

FOR AUTHOR USE ONLY

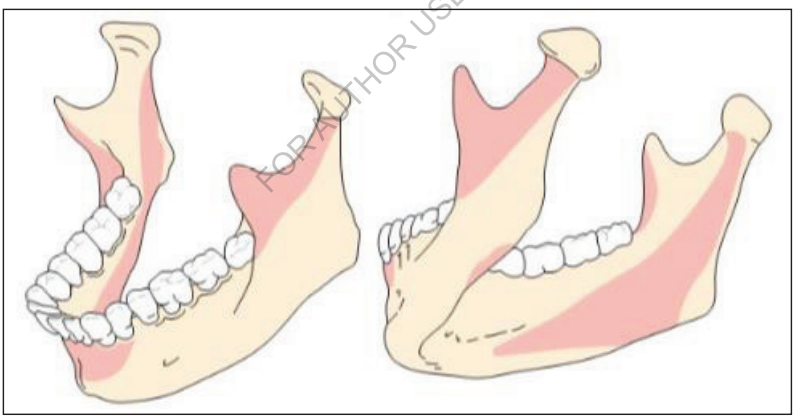

Fig 13. Mandibular remodelling-Resorptive surfaces are dark shaded and depository surfaces are unshaded. (Taken From Moyers R. Growth of the craniofacial skeleton. In: Handbook of Orthodontics. 4th ed. Chicago: Year Book Medical Publishers;1988.)

This is because the condyle is quite broad and the neck is narrow. The endosteal surface of the neck actually faces the growth direction; the periosteal side points away from the course of growth. This is another example of the V principle, with the V-shaped cone of the condylar neck growing toward its wide end as shown in Figure-14.[2]

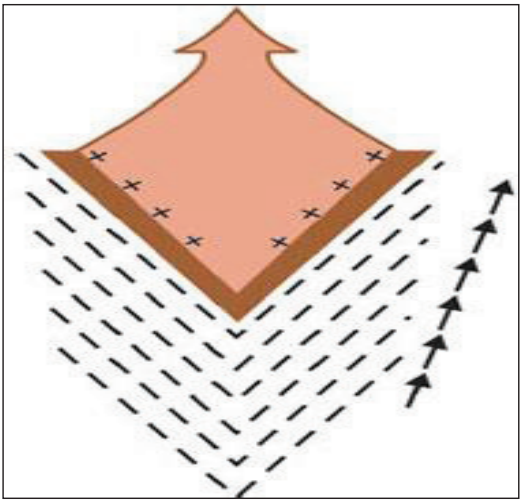

Fig 14. V principle- Bone deposition occurs on the inner side of the V; resorption takes place on the outside surface. The V thereby moves from position A to B and at the same time, increases in overall dimensions. The direction of movement is toward the wide end of the V. (Taken from Enlow D, Hans M. Essentials of facial growth. Philadelphia, London, Toronto: W.B. Saunders;1975.)

FOR AUTHOR USE ONLY

As growth progresses, bone from one level in the condyle-upper ramus region, gets incorporated into the next level lower down.

In sequence: Condylar head parts incorporated into new upper Condylar neck.

- Upper parts of the neck undergo remodelling conversion into the new lower parts.
- The lower portions receive direct remodelling changes into the ramus proper.

The successive growth movements involve the principle of 'area relocation', which

represents the basic factor that underlies these remodelling processes. With each successive addition of new bone at the free end of the condyle, all the levels down the line in the neck and ramus necessarily receive relocation in their relative positions. Each local level, as it becomes repositioned, undergoes adjustments in shape and dimensions to convert it into the next level in sequence.[25] As condylar and ramus development proceeds, the mandible as a whole, is becoming displaced antero-inferiorly as shown in Figure-15.

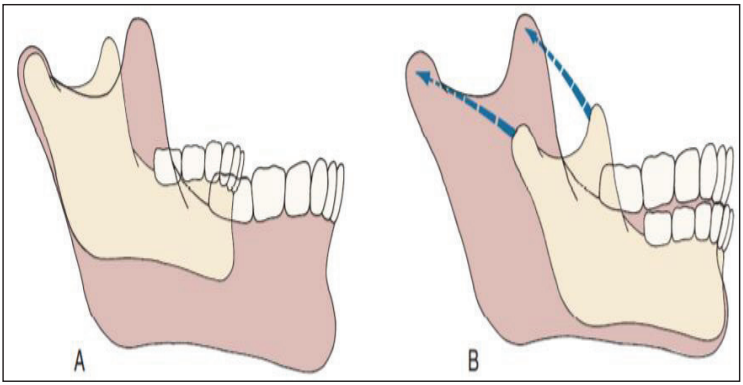

Fig 15. The condyle enlarges directly toward its articular contact in the glenoid fossa of the cranial floor. As this takes place, the whole mandible is moved forward and downward by the same amount that it remodels upward and backward (Taken from Proffit WR, Fields Jr HW. Later stages of development. In: Proffit WR. Contemporary Orthodontics. 5th ed. St Louis, MO: Mosby;2000:p.87-104.)

What is the physical force that produces the forward and downward primary displacement of the mandible?

For many years it was presumed that growth of the condylar cartilage, because it is known that cartilage is a special pressure-adapted type of tissue, creates a "thrust" of the mandible against its articular-bearing surface in the glenoid fossa. The proliferation of the cartilage toward its contact thereby was presumed to push the whole mandible away from it.

FOR AUTHOR USE ONLY

The Condylar head

The condylar head is much broader than the neck beneath it, because the neck is sequentially derived from the head by remodeling , a marked reduction in width takes place as shown in Figure-16.

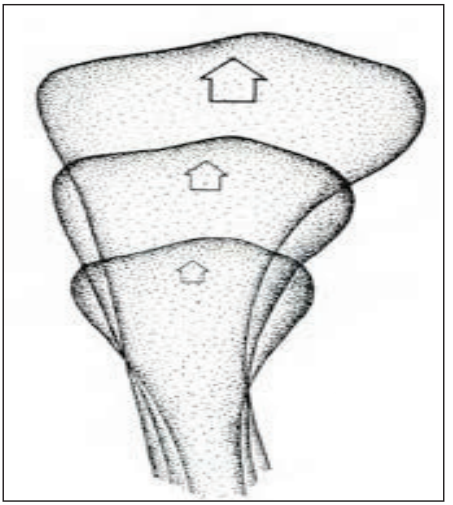

Fig 16. The diameter of the narrow condylar neck is progressively reduced from the wider dimensions of the posterior moving condyle. (Taken from Enlow, DH & Harris DB. A study of the postnatal growth of the human mandible. Am J Orthod Dentofac Orthop 1964;50(1): 25-50.)

FOR AUTHOR USE ONLY

Reduction is brought about by surface resorption of bone on periosteal side of the cortical plate together with continued, proportionate deposition of bone on the endosteal surface.

The entire cortex drifts in an endosteal direction as

(1) The head moves progressively away from the existing neck, and

(2) The neck becomes lengthened by this process of endosteal growth behind the mov ing head.

The buccal and lingual cortical plates move in an inward, medullary direction toward each other as the transverse dimensions of the neck become reduced. The growth and remodelling process in the condylar neck follow the V principle. New bone is added to the inner side of the V shaped neck while bone is removed from the outer (periosteal) surface at the same time as shown in Figure-17.[26]

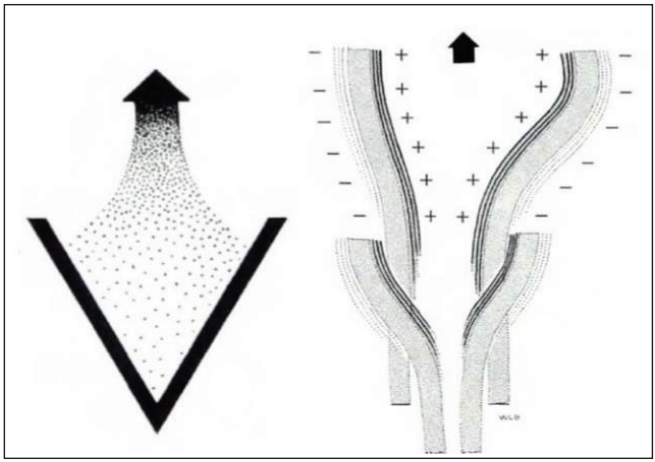

Fig 17. Inward growth of the buccal and lingual cortices is accomplished by a combination process of periosteal resorption (-) and endosteal deposition (+) . This is an example of the V principle. (Taken from Enlow, DH & Harris DB. A study of the postnatal growth of the human mandible. Am J Orthod Dentofac Orthop 1964;50(1): 25-50.)

FOR AUTHOR USE ONLY

The V mechanism of remodelling provides three simultaneous growth functions

1. It moves the entire structure in a progressive course toward its free (wide) end, cau sing a continuous change in position of the condyle and neck to keep pace with the moving condylar growth cartilage.

2. Second, it produces an overall enlargement of the whole V shaped region proportionate to the increasing size of the mandible as a whole.

3. Third, it results in a sequential reduction of the tapering wide part of the head and neck into more narrow areas as the latter becomes relocated into the former. This reduction is produced by cortical growth in an endosteal manner. The growth principle dealing with surfaces facing toward and away from the direction of growth applies.[27]

In summary, the condyle rather than acting as a "master growth center," actually performs in a much more functional role. It provides a pressure-tolerant articular contact and it makes possible a multidimensional growth capacity in response to ever-changing developmental conditions and variations.

BIOMECHANICAL AND BIOCHEMICAL DEVELOPMENT OF THE CONDYLAR BONE

Bone constantly strives for optimal architecture. Mandibular condyle, which is subjected to various mechanical loads forcing it to be highly adaptive, has a unique structure and a relatively high remodelling rate and maintains an optimal architecture withstanding forces with the least material possible. Mandibular condyle adjusts its architecture to these specific, mostly compressive loading in supero-inferior direction with the articular surface supported for the most part by vertically oriented trabeculae.[28]

Biomechanical consequences of developmental changes

(i) The role of the mineralized component in the apparent bone mechanical properties

Bone density influences bone stiffness at the apparent level, yield stress, and ultimate stress. Bone trabeculae decrease in number and increase in thickness during prenatal development, resulting in an increase in bone density. Additionally, anisotropy matters as bone is stiffest in the direction in which its elements are aligned.[29] Bone stiffness is correlated positively to its mineralization degree too. Within physiologic limits, mineral content and ultimate strength are correlated positively. Osteoporotic bones show low bone density and high mineral content as apposition of new, lowly mineralized, tissue is limited. The higher mineralization in the cores of condylar trabeculae and the concomitant remodelling-related low mineralization at the bone surfaces result in a heterogeneous mineral distribution.

FOR AUTHOR USE ONLY

(ii) The role of collagen in the apparent mechanical properties of bone

The amount of collagen is positively correlated to toughness, to tensile strength when tested parallel to the main collagen fibre orientation, to compressive and bending strength when tested perpendicular to the main collagen fibre orientation, and to post-yield properties of bone.[30] The more the collagen fibres are aligned, the larger are potential bone microfractures in the collagen fibres main direction. Changes in collagen content, fibre orientation, and the number of HP, LP, and Pen cross links correlate with bone stiffness measurements, but experimentally altered numbers of HP, LP, and Pen cross links do not change apparent bone stiffness.[31]

(iii) The role of the mineralized bone component in the micromechanical properties of bone

Micromechanical properties of bone can be studied at the level of single bone trabeculae using highly accurate and non-destructive methods such as, atomic force microscopy and nanoindentation. The correlation between local mineralization degree and local bone tissue stiffness is positive but highly variable with coefficients of determination ranging from 0.07 to 0.94.[32] In addition, local mineralization degree might affect fracture risk and mechanical properties at the apparent level.[33]

(iv) The role of collagen in the micromechanical properties of bone

Collagen fibre orientation has a marked local influence on the micromechanical properties of bone in compression. The collagen cross links probably play a negligible, if any, role in bone micromechanical properties.[32]

(v) Biomechanical consequences of developmental changes of mandibular condyle

Bone of the aging condyle is characterized by a decrease in mineralization heterogeneity. A sharp rise of the mean mineralization degree of bone, might occur during aging has adverse effects on the mechanical properties.[34] The apparent stiffness of condylar bone is raised by the increase in the degree of mineralization, the decrease in the degree of anisotropy, and the transition from the rod-like to the plate-like trabecular shape. The latter shape changes and the reduction of the number of HP, LP, and Pen may enhance the post-yield and ultimate stress characteristics of condylar bone as shown in Figure-18.

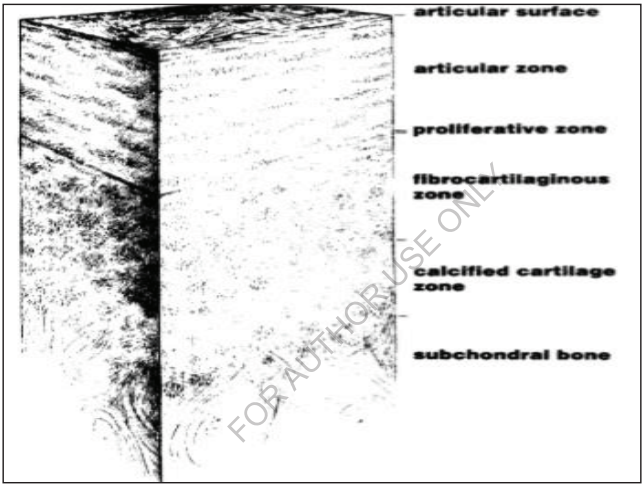
Biochemical composition of the mandibular condylar cartilage

Articular cartilage contains chondrocytes and a large amount of surrounding matrix macromolecules such as proteoglycans, glycosaminoglycans (GAGs) and type II, IX, and XI collagens. These molecules contribute to the flexibility of cartilage and protection of the joint components from mechanical threats originating from compression, shearing and stretching loads. The load-bearing functions of cartilage are mainly provided by the viscoelastic property of collagen fiber network and the osmotic pressure due to the presence of proteoglycans. The mandibular condylar cartilage consists largely of fibrocartilage, with thick multi-layers composed of several collagen fiber zones as shown in Figure-19.[35]



FOR AUTHOR USE ONLY

Fig 19. Diagram of the spatial arrangement of collagen fibrils in the articular cartilage of the mandibular condyle.(Taken from De Bont LGM, Boering G, Havinga P & Liem RSB. Spatial arrangement of collagen fibrils in the articular cartilage of the mandibular condyle: A light microscopic and scanning electron microscopic study. J Oral Maxillofac Surg, 1984;42(5):306-313.)

The collagen fibers are considered to provide mainly tensile strength to the cartilage. Shear strength has been suggested to originate from cross-links between the collagen fibers.[36] In the mandibular condylar cartilage, collagen fibers run mainly in the antero-posterior direction, which is suggested to be an optimized orientation to resist antero-posterior shear forces.[37]

FACTORS REGULATING MANDIBULAR CONDYLAR GROWTH

Petrovic and Stutzmann (1975) hypothesized that "There must be a negative feedback-signal originating from the proximal part of the chondroblastic zone and exerting a restraining effect on the prechondroblastic multiplication rate."[38] Condylar growth must be regulated by a host of orchestrated influences of various growth factors and other regulatory factors that are endogenously expressed in the condyles.

Several factors have been verified to have great impact on growth and development of mandibular condyle. They are:

i) Sox9 and type II collagen

The transcription factor Sox9 [Sex-determining Region on the Y Chromosome (SRY)-related High-Mobility Group (HMG) Box 9] plays a key role in chondrocyte differentiation.[39] Sox9 regulates chondrogenesis in two ways. Firstly, it is essential in the progress that mesenchymal cells differentiate into chondrocytes. Secondly, Sox9 regulates condylar cartilage formation by modulating the expression of Col2a1 (Core binding factor alpha 1)-encoding type II collagen, the most abundant structural collagen component of cartilage, together with other elements of cartilage-specific extracellular matrix (collagens IX, XI, the large proteoglycan aggrecan, etc). Rabie and Hagg (2002) found that during natural growth of rats condyles, Sox9 was expressed in mesenchymal cells and chondrocytes, indicating its similar effects on regulating mesenchymal cells differentiation and cartilage formation.[5]

FOR AUTHOR USE ONLY

When the mandible is positioned forward, there is an up-regulation of the expression of Sox9 as well as type II collagen in the condyle and the glenoid fossa, resulting in an increased amount of cartilage formation and subsequent new bone deposition.[40,41]

ii) Parathyroid hormone-related protein

It was hypothesized that Sox9 was a target for PTHrP signaling. PTHrP was observed to up-regulate Sox9, the factor regulating the differentiation of mesenchymal cells into chondroblasts. Therefore, it was suggested that PTHrP may induce the differentiation of mesenchymal cells through the Sox9 pathway.

It was found that forward positioning of mandible triggered the expression of PTHrP, which led to an increased number of differentiated chondroblasts and retardation of chondrocyte hypertrophy, followed by increased cartilage volume. Therefore, through functional appliance therapy, the condyle is endowed with more potential to construct the cartilage frame for future endochondral bone deposition.[42]

iii) Indian hedgehog

Indian hedgehog (Ihh) plays a key role in proliferation, hypertrophy and apoptosis of chondrocytes.

Mandibular advancement stimulated the expression of Ihh in condylar cartilage resulting in an increased number of proliferating mesenchymal cells and a shortened turnover time. Ihh may mediate the conversion process of the mechanical signals caused by mandibular advancement into cellular replication in condylar cartilage.[43]

iv) Fibroblast growth factor and its receptors

The fibroblast growth factor receptors (FGFRs) are known to have a significant impact on the growth and development of cartilaginous tissues.[44] In mandibular condyle, chondroblasts and hypertrophic chondrocytes showed the most pronounced immunoreactivity for receptors of FGF-2, including FGFR1 and FGFR3.

Designed to create a lateral functional shift of the mandible, intraoral appliances bring about a transverse rotation of the mandible with the condyle on the shifting side remaining in place or moving slightly posteriorly (non-protruded) while the opposite site distracted anteriorly (protruded) from the glenoid fossa. There were significant differences in gene expression for FGF-2, FGFR1, FGFR2 and FGFR3 between the protruded and non-protruded condylar cartilage.

FOR AUTHOR USE ONLY

v) Type X collagen

Type X collagen, secreted by hypertrophic chondrocytes, is recognized as an indicator for endochondral ossification and bone replacement of the cartilage matrix.[45] Therefore, it was considered as a unique element of the hypertrophic cartilage matrix and a critical marker for endochondral bone formation.

When the mandible is positioned forward by functional appliances, intensive expression of type X collagen is found to distribute throughout the hypertrophic zone when compared with the controls, indicating the onset of condylar endochondral bone formation stimulated by the functional appliances therapy.

vi) Vascular endothelial growth factor

Vascular Endothelial Growth Factor (VEGF) is known to be a potent regulator of neovascularization.[46]

VEGF also plays an important role in regulating endochondral ossification in condyles by controlling neovascularization.

Besides hypoxia, Upon forward mandibular positioning by bite-jumping appliance, there was a significant up-regulation of VEGF, followed by accelerated vascularization and subsequently increased new bone formation in both the condyle and glenoid fossa.[47,48] It was found that the temporal expression of VEGF was correlated with the pattern of new bone formation in condyle and glenoid fossa during stepwise mandibular advancement. In comparison with one-step advancement, the initial advancement in the stepwise group, demonstrated significantly less expression of VEGF. However, rf VEGF expression appeared to increase significantly, in the stepwise group when compared with the single advancement group and the natural growth group. This result suggested that the mechanical stimuli provided by stepwise mandibular advancement may trigger a sequence of cellular events resulting in increased vascularization and bone deposition in condyle. [49,50]

Vii) Core binding factor alpha 1/ Runt-related transcription factor 2

Core binding factor alpha 1 (Cbfa1), also known as Runt related transcription factor 2 (Runx2), serve as a key regulator of condylar cartilage development, osteoblast differentiation and bone matrix deposition.[51] Rabie et al. (2004) found that during the natural development of mandibular condyle, the peaking of Cbfa1 level coincides with chondrocyte hypertrophy and matrix mineralization.[52] Mandibular advancement triggers Cbfa1/Runx2 expression in condylar cartilage, resulting in increased osteoblasts invasion and stimulated chondrocyte terminal maturation.[53]

FOR AUTHOR USE ONLY

viii) Osteoprotegerin / Receptor activator of NF-kappaB ligand

Receptor activator of NF-kappaB ligand (RANKL) which belongs to the tumor necrosis factor superfamily together with osteoprotegerin (OPG). The ratio of OPG/RANKL plays a major role in the regulation of osteoclastogenesis: an increased ratio leads to a reduced number of newly formed osteoclasts and vice versa.[54] A decrease of chondrocytes secreted OPG/RANKL ratio and decrease of OPG level was observed, suggesting its critical role in the osteoclastogenesis of mandibular condyle. However, functional appliances effects on endochondral ossification in mandibular condyle, achieved by coordination between osteoblasts and osteoclasts still needs to be obtained with the introduction of OPG and RANKL.

ix) Insulin-like Growth Factors

The insulin-like growth factors (IGFs or somatomedins) are a family of low molecular weight peptides (mass about 7.5 kDa). Two main isoforms of IGF (IGF1 and IGF-2) are respectively composed of 70 and 67 amino acid residues.

Several roles to IGF-1 have been attributed in the growth of the mandibular condyle:

a) It facilitates in vitro proliferation of the cartilaginous cells in condyles.
b) It enhances synthesis of PG and maintains an expression for the synthesis of type II collagen in the absence of serum.
c) It stimulates the replication of osteoblasts and synthesis of the bone matrix.
d) It blocks cytokine-stimulated cartilage degradation in a manner comparable to that of TGF-b-1.
e) It participates in the control of cartilage homeostasis in the orofacial area.
f) IGFs regulate cartilage growth and differentiation.
g) IGFs are involved in the growth and development of teeth, mandibles, maxilla and tongue in the oro-facial area.[4]

x) Matrix-mettalo-proteinases

MMPs being a family of proteolytic enzymes, regulating cell differentiation and tissue remodeling, they are secreted by most types of cells, with their expression transcriptionally regulated by the growth factors and cytokines.[55] Consequently, they allow

(1) Cell migration

(2) Cell attachment

(3) Proliferation

(4) Differentiation

(5) Alteration in the ECM micro-environment

(6) Induction in the altered cellular behavior, and

(7) Morphogenesis.

The administration of growth factors along with the use of mandibular advancement appliance has increased genetic expression of MMP-1 and MMP-13 supported by histomorphometric evidence indicating growth of condylar cartilage.[56]

INCREMENTAL GROWTH CHARTS FOR CONDYLAR GROWTH

Dimensional changes

For the three planes of space in both the maxilla and mandible, there is a definite sequence in which growth is "completed". Growth in width is completed first, then growth in length, and finally growth in height. Growth in length and height of both jaws continues through the period of puberty.

Sexual dimorphism in condylar growth was clearly indicated. Male condyles grew at slightly faster rates during childhood and at substantially faster rates during adolescence, for other craniofacial measures.[57,58] Baumrind and co-workers (1992) reported relatively constant rates of condylar growth for a sample of treated and untreated children between 8.5 and 15.5 years of age, although sex differences in growth patterns were identified.[59]

During later childhood and adolescence, the condyle shows substantially greater amounts of superior than posterior growth. For every 1mm of posterior growth, there is 8 to 9 mm of superior growth. [60] It has been estimated that the condyles of females and males grew 2-2.5 and 2.5 to 3.0 mm/yr respectively, during childhood and adolescence, with the greatest rates occurring during the earlier childhood years and during the adolescent spurt as shown in Figure-20[a,b].

FOR AUTHOR USE ONLY

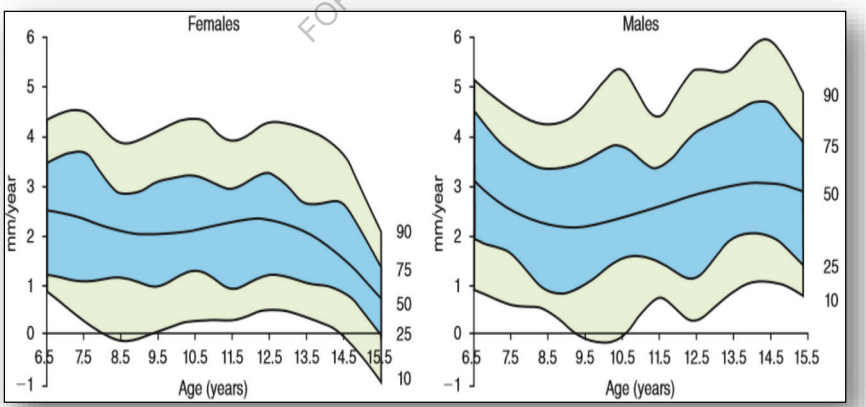

Fig 20. (a) Total condylar growth. Incremental chart for females. **(b)** Total condylar growth. Incremental chart for males.(Taken from Buschang PH, Santos-Pinto A & Demirjian A. Incremental growth charts for condylar growth between 6 and 16 years of age. Eur J Orthod 1999;21(2):167-173.)

Dimorphism in the timing of the adolescent spurt (12.2 years and 14.3 years for females and males, respectively) coincides with estimated ages of peak adolescent velocity reported for other craniofacial and somatic measures.[61,62] This suggested that some children exhibit negative growth velocities, especially around the prepubertal minimal growth period and towards the end of adolescence. This may be due to structural bony changes in the mandibular condyle associated with craniomandibular disorders, such as osteoarthosis, osteoarthritis, and polyarthritis. Such structural bony changes in approximately 5 per cent of a sample followed between childhood and adulthood.[63]

The data provides a means for monitoring treatment outcomes, making it possible to more accurately evaluate the response of condylar growth to treatment and also help orthodontists to identify children who require further investigation or therapy, Since the majority of patients with Class II and Class III skeletal malocclusions had abnormal mandibular growth and the condyles are the foci of treating mandibular growth problems.[64] They provide standards against which individual patient's past growth can be assessed.

FOR AUTHOR USE ONLY

Conclusion

- The condyles follow the general or somatic pattern of growth with childhood deceleration, acceleration during adolescence to peak velocity, and rapid deceleration after the peak.
- There is sexual dimorphism in condylar growth. Females have less intense rates of condylar growth, especially during adolescence, than males and they attain peak adolescent velocity approximately 2 years earlier than boys.
- There is substantial individual variation in condylar growth. Some individuals had little or negative growth, while others showed more than 5 mm of growth per year.
- The data provides an objective means of evaluating patient's growth potential and treatment outcome.

ROLE OF ANGIOGENESIS IN CONDYLAR GROWTH

Introduction

Angiogenesis is the crucial step in mandibular condylar growth for it regulates the transformation from cartilage to bone.

According to Rabie *et al.* (2003) several factors play important roles during the condylar process. Sox 9 regulates the synthesis of type II collagen, type IX collagen, type XI collagen and aggrecan and it is the target of PTHrp signalling.[40]

On this basis, a feedback model is suggested for:

(i) Progressive growth of avascular epiphyseal cartilage which leads to a state of increased hypoxia that up-regulates VEGF expression.
(ii) Its control by the diffusion of soluble VEGF isoform(s) from the hypoxic center towards the periphery to induce epiphyseal vessel outgrowth and thereby reduce the hypoxic stress. Subsequently, VEGF induces an invasion of vessels into the cartilage to initiate secondary ossification. Thus, growth initiation and growth control has an auto-signaling mechanism as depicted in Figure-21.[65]

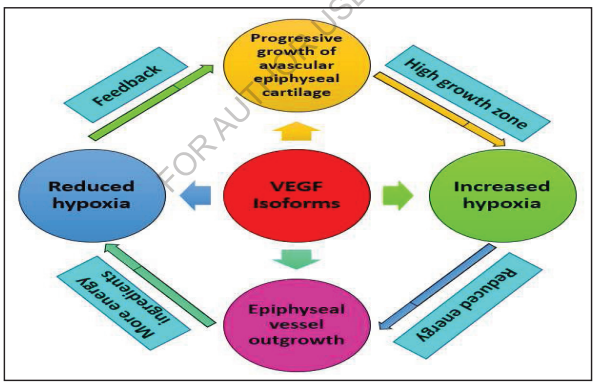

Fig 21. Feedback model of VEGF isoforms to initiate and control hypoxic condition during angiogenesis.(Taken from Patil AS, Sable RB, Kothari RM. Occurrence, biochemical profile of vascular endothelial growth factor (VEGF) isoforms and their functions in endochondral ossification. J Cell Physiol 2012;227:1298-1308.)

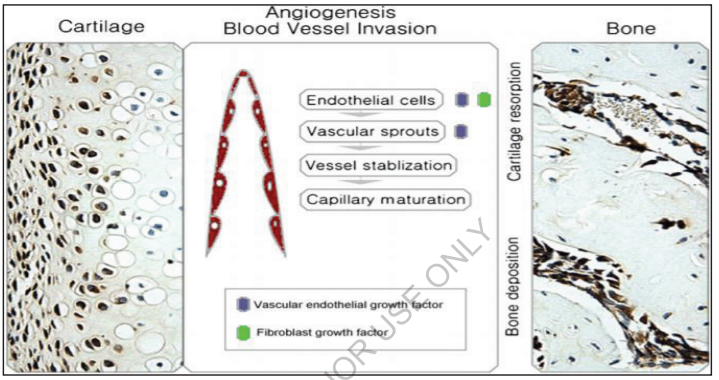
The role of angiogenesis in condylar growth

Condylar cartilage has a dual structure, a thick fibro-articular area for appositional growth and a deeper hyaline-cartilaginous area for interstitial growth. This is important in bearing the compressive stress transmitted to the condyle during mandibular movement and growth. Vascular invasion is prerequisite for bone formation.

Osteogenesis, which is the formation of the new bone and angiogenesis, which is the invasion of new blood vessels, are closely related processes.[66] Blumer *et al.* (2005) investigated that Growth of cartilage canals into the secondary ossification centre was improved by VEGF. The canals contained chondroclasts which opened the lacunae of hypertrophic chondrocytes. The following process was the invasion of mesenchymal cells into the empty lacunae and formation of an osteoid layer. The accelerated cartilage resorption was possibly due to new blood vessel invasion, which leads to the recruitment of chondroblasts into the area of bone formation.[67] These two processes may act together to enhance bone formation as shown in Figure-22.



FOR AUTHOR USE ONLY

Fig 22. Illustration of the process of condylar growth-blood vessel invasion transformed condylar cartilage into bone. Left: cartilage layers, VEGF Immunostaining, the brown spots show the distribution of VEGF. Middle: endothelial cells migrate towards the stimulus such as VEGF and FGF, proliferating to form vascular sprouts and eventually form a lumen. Right: Formed new bones. VEGF Immunostaining. Brown spots show the distribution of VEGF.(Taken from Li Q, Rabie A. A new approach to control condylar growth by regulating angiogenesis. Arch Oral Biol 2007;52(11):1009-1017.)

Mandibular protrusion leads to an increase in the number of mesenchymal cells in the mandibular condyle and glenoid fossa. The more mesenchymal cells will bring more bone formation. Thus, VEGF-dependent new blood vessel recruitment is essential for coupling cartilage resorption and mineralized bone formation during the process of endochondral ossification in bone development.[68] Blood vessel invasion of cartilage, which is normally avascular, is the first crucial step in this process.

From cartilage to bone, angiogenesis leads the way.

Angiogenesis regulators

a) Vascular endothelial growth factor

VEGF can enhance neovascularization and create the new blood supply required for bone formation. It can also help with the differentiation of osteoprogenitor cells.[69] These substances can guide the differentiation of mesenchymal cells by making them enter the osteogenic pathway and further engage in osteogenesis.

b) Fibroblast growth factor

FGF is important in the initial vascularization of the healing process in bone graft.[70] The FGF receptors (FGFRs) represent a family of four tyrosine kinase receptors (FGFR 1–4) that bind FGFs with variable affinity. FGF 1,2,4,8,9 and particularly 18, which is produced by the perichondrium, bind and activate FGFR3 with high affinity.

Angiogenesis inhibitors

Angiogenesis inhibitors can be mainly divided into four groups: endogenous naturally occurring inhibitors, exogenous angiogenic inhibitors, VEGF ligands antibodies and VEGF receptor inhibitors.

1) Endogenous naturally occurring inhibitors

Three naturally occurring inhibitors are angiostatin, endostatin and thrombospondin.

FOR AUTHOR USE ONLY

a) Angiostatin

Angiostatin can act as an anti-angiogenesis factor in several aspects. Firstly, angiostatin can inhibit endothelial cell proliferation. Secondly, angiostatin can induce endothelial cell apoptosis. Thirdly, angiostatin can inhibit endothelial cell migration and invasion. On the contrary, it had little effect on VEGF expression or it can increase its expression because of hypoxia in the tumour tissue.

b) Endostatin

Endostatin is a 20 kDa C-terminal cleavage product of collagen XVIII that belongs to the multiplexin family and is characterized by multiple triple-helix domains and interruptions.

c) Thrombospondin

Thrombospondin (TSP), a 450 kDa matricellular protein, was the first anti-angiogenic factor discovered in 1990s. TSP prevented VEGF-induced angiogenesis and induced endothelial cell apoptosis.

2) Exogenous angiogenic inhibitors

TNP-470 (or AGM-1470) is a synthetic derivative of fumagillin that inhibits methionine aminopeptidase-2, a cytoplasmatic enzyme of endothelial cells, cell proliferation and cell migration, thus blocking capillarogenesis and angiogenesis. It was one of the first antiangiogenic agents to enter clinical trials (entering human testing in 1992).

Thalidomide was originally marketed about 40 years ago as a sedative, and its widespread use by pregnant women led to the discovery of its teratogenic effects. It is apoptogenic for neovasculature and inhibits angiogenesis.

a) VEGF antibodies and VEGF receptor inhibitors

VEGF antibodies such as Avastin Bevacizumab (Avastin), anti-VEGF antibody 2C3,VEGF-Trap and VEGF receptor inhibitors such as SU5416 had shown to contain toxicities.

Promising strategies to regulate condylar growth

a) Nanotechnology

FOR AUTHOR USE ONLY

Nanobiotechnology is a recently coined term describing the convergence of the two existing but distant worlds of engineering and molecular biology.[71] Nanovector liposomes had been used successfully for the therapy of breast cancer.

b) Artificial cells, cell encapsulation and stem

Encapsulated hepatocytes was used as a model for cell and gene therapy. Cells in capsules produce proteins that can provoke inflammatory responses in immune cells and that this even occurs with isografts. Another possibility is that inflammatory cell response results from using standard method for cell encapsulation, which leads to a few cells protruding on the surface of artificial cells. Stem cells was recognized as another possible therapeutic approach because they can differentiate into different types of cells.

c) Gene therapy

Gene therapy is a technique used to deliver small DNA or RNA sequence to cells or tissues to correct a genetic defect or treat a disease. rAAV is a group of nonpathogenic, replication-defective small DNA viruses. Rabie's research group (2007) has proved that compared with rAAV1, rAAV5, rAAV6 and rAAV8, rAAV2 has the highest infection efficiency for the transduction of primary cultured chondrocytes.[72]

ROLE OF FUNCTIONAL APPLIANCE THERAPY IN CONDYLAR GROWTH

Biomechanical force produced by mandibular forward positioning provokes cellular and molecular responses in the temporomandibular joint (TMJ) of growing animals, leading to condylar and glenoid fossa growth.[73] Forward mandibular positioning precipitates a series of changes in the level of expression of these factors that leads to condylar growth in growing rats, particularly the level of expression of type II collagen, the major collagenous framework of cartilage as well as the level of expression of type X collagen, the major component of the hypertrophic cartilage matrix.[40]

Retrognathic mandible and increased lower facial height are common features in patients with Class II malocclusion.[64] Functional appliance therapy in growing patients should thus aim to increase mandibular prognathism without a detrimental effect on facial height.

The cellular and molecular events participating in bone formation in the condyle gave the data for the changes in condylar growth in response to functional appliance therapy. If the effect of functional appliance therapy on condylar growth is acceleration, then the expression of factors regulating key processes in condylar growth should be accelerated when compared with their expression during natural growth. If the effect of functional appliance therapy was actual growth, then the cartilage matrix and the amount of bone formed during mandibular advancement should be more than the amount of bone formed during the same period of natural growth. A true enhancement of growth in response to functional appliance therapy i.e. an actual increase in growth that should not have occurred, relies on maintaining the increase in bone formation in the posttreatment period until the end of the pubertal growth period.

FOR AUTHOR USE ONLY

Histologic changes in the condylar cartilage after anterior translation of the mandible

After 1 week of treatment with a hyperpropulsor, the cell proliferation zone in the rat cartilage is thickened without producing noticeable changes in the cartilage zone.

Not until the appliance has been worn for 4 weeks can the cell proliferation zone and the cartilage zone be seen as significantly wider as shown in Figure-23.

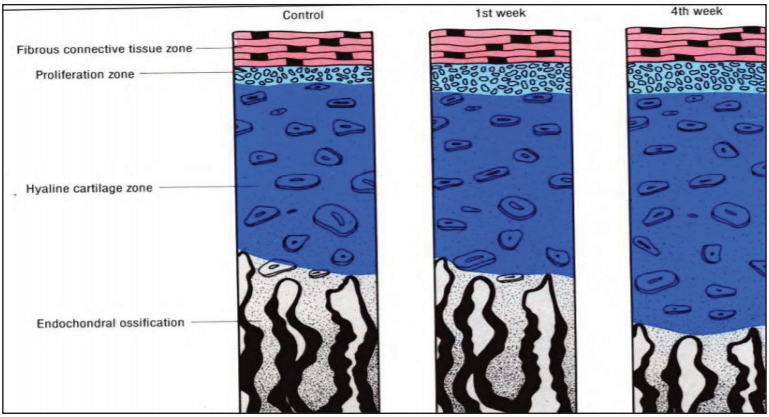


Fig 23. Histologic changes in the condylar cartilage after anterior translation of the mandible.(Taken from Rakosi T, Jonas I, Graber T. Color atlas of dental medicine - orthodontic diagnosis. Shenyang: Liaoning ke xue ji shu chu ban she;2000.)

Histologic changes in the condylar cartilage after posterior translation of the mandible

After 1 week of treatment with a chin cap, the cell proliferation zone in the rat cartilage is narrowed.

After wearing the chin cap for 4 weeks the height of the cartilage zone has also decreased. This change therefore appears to be secondary, as a result of the reduced number of undifferentiated cells in the proliferation zone, which later become differentiated to chondroblasts as shown in Figure-24.[38]

FOR AUTHOR USE ONLY

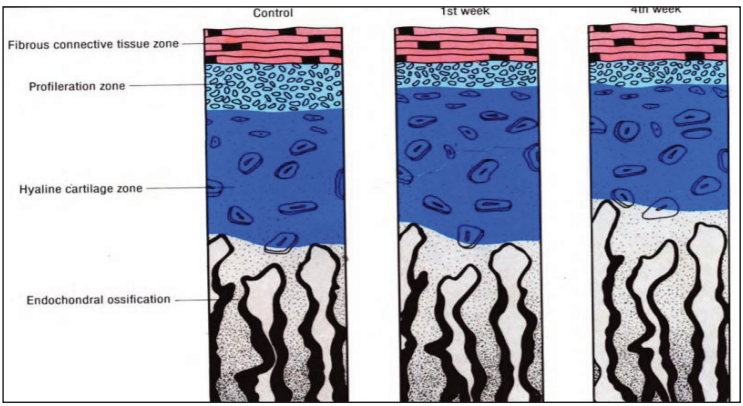

Fig 24. Histologic changes in the condylar cartilage after anterior translation of the mandible.(Taken from Rakosi T, Jonas I, Graber T. Color atlas of dental medicine - orthodontic diagnosis. Shenyang: Liaoning ke xue ji shu chu ban she;2000.)

There are consistent reports that treatment with fixed functional (Herbst) appliances increases the extent of mandibular prognathism compared with no treatment.[74,75]

In experimental studies, the condyle's response to forward repositioning of the mandible is enhanced growth and significantly more so with stepwise advancement than with maximum jumping of the mandible. In particular, stepwise mandibular advancement tends to lead to more prognathism than does maximum jumping.[76] An early study showed that treatment with the Herbst appliance enhanced sagittal but not vertical condylar growth.[77] Treatment with a headgear-Herbst appliance for 12 months of stepwise advancement has been shown to achieve more mandibular prognathism and less lower face lengthening than in untreated controls.[74] In contrast, in a study of a headgear-activator with maximum jumping of the mandible, neither growth of the lower face nor mandibular prognathism was affected.[78]

Studies of patients treated with the Twin-block appliance for 7 months[19] and the Herbst appliance for 12 months[14] found no differences in mandibular prognathism when stepwise advancement of the mandible was compared with maximum jumping.[76]

FOR AUTHOR USE ONLY

Pancherz *et al.* (1998) reported that, after 7.5 months of treatment, an effect on mandibular prognathism was observed, but it vanished completely 7.5 months after the Herbst appliance was removed.[79] That temporary result might be because of insufficient retention and insufficient treatment time to allow newly formed bone to mature.[80,81]

According to Mills and McCulloch (2000), whose use of the Twin-block appliance resulted in an average increase in mandibular length during active treatment. In the posttreatment period, there was a slight reduction in the mandibular growth rate, but most of the increase in mandibular length achieved during treatment was still evident 3 years later.[82]

Therefore, Forward mandibular positioning accelerates and enhances chondrocyte differentiation and cartilage matrix formation in the mandibular condyle by accelerating and enhancing the expression of Sox 9 and type II collagen and osteogenesis in the mandibular condyles and also mandibular advancement led to a significant increase in the amount of bone formed in the posterior part of the condyle. Various modes of advancing the mandible during functional appliance therapy affect condylar growth differently, specifically stepwise mandibular advancement vs maximum mandibular jumping.

GROWTH RELATIVITY HYPOTHESIS FOR CONDYLAR GROWTH

Understanding mechanisms of action for orthopedic appliances is critical for orthodontists who hope to treat and retain the achieved corrections in patients with initial Class II mandibular retrognathism. That knowledge can help orthodontists produce clinically significant bone formation and avoid compression at the condyle-glenoid fossa region.

Growth relativity hypothesis

Hypothesis presented for the mechanism of condylar-fossa growth modification with propulsive mandibular appliances, such as the Herbst & Twin-block.

Growth relativity refers to growth that is relative to the displaced condyles from actively relocating glenoid fossae.

How condylar modifications occur ?

FOR AUTHOR USE ONLY

Over the years several theories have emerged attempting to shed light on condylar growth. These are-

a) Genetic theory

One of the earliest theories, the genetic theory, suggests the condyle is under strong genetic control that causes the entire mandible to grow downward and forward.[83] Although this may be related more to development of prenatal than postnatal condylar growth, this theory does indirectly question the effectiveness of orthopedic appliances in condylar growth as proposed by Brodie (1946).[84]

b) Lateral pterygoid hyperactivity hypothesis

The masticatory muscles, particularly the lateral pterygoid has aroused considerable orthodontic interest. Petrovic *et al.* (1975) raised the possibility that the lateral pterygoid activity increased the proliferation of condylar tissue.[85]

McNamara (1973), using protrusive bite planes and temporary acute electromyographic (EMG) electrode placements found that activity in the superior head of the lateral pterygoid muscle could be directly or indirectly correlated with gradual skeletal adaptations.[86] More recently, after an extensive review of the literature, Johnston (1996) concluded that the lateral pterygoid muscle hyperactivity hypothesis is incorrect.[87] Rees (1954) reported that other muscles and tendons including those of

the deep masseter and temporalis, also attach to the articular disk region.[88] Attachments of lateral pterygoid muscle to the condylar head or articular disk may expected to cause condylar growth but an anatomic research has not found evidence that significant attachments actually exist as shown in Figure-25 [A,B].

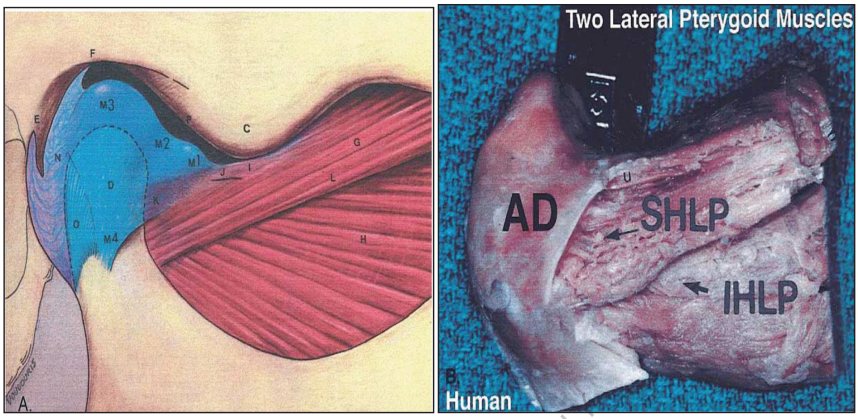

Fig 25. (A) Three-dimensional illustration of unadvanced human TMJ shows minimal attachment (J) of superior head of the lateral pterygoid muscle to articular disk (M1, blue) and retrodiskal tissue complex (N). **(B)** Clean, representative TMJ dissection from human adult cadaver specimen to expose the pterygoid muscles. Fascia and tendon of a small upper proportion (u) of SHLP fibers are firmly attached to stabilize the articular disk from the posteriorly attaching retrodiskal tissues that continue to be extended at the start of closing (not shown). It is important to note the majority of both the SHLP and inferior head of the LPM (IHLP) fibers attach lower to the neck of the condyle (arrows) and not the articular disk or condylar head. (Taken from Voudouris JC, Kuftinec MM. Improved clinical use of Twin-block and Herbst as a result of radiating viscoelastic tissue forces on the condyle and fossa in treatment and long-term retention: growth relativity. Am J Orthod Dentofac Orthop 2000;117:247-66.)

FOR PREVIEW ONLY

More recently, permanently induced implanted longitudinal muscle monitoring techniques have found that the condylar growth is actually related to decreased postural and functional lateral pterygoid muscle activity.[89] This notion was also supported in human studies by Auf der Maur (1980),[90] Pancherz and Anehus Pancherz (1980),[91] and Ingervall and Bitsanis (1986),[92] who reported decreased muscle activity.

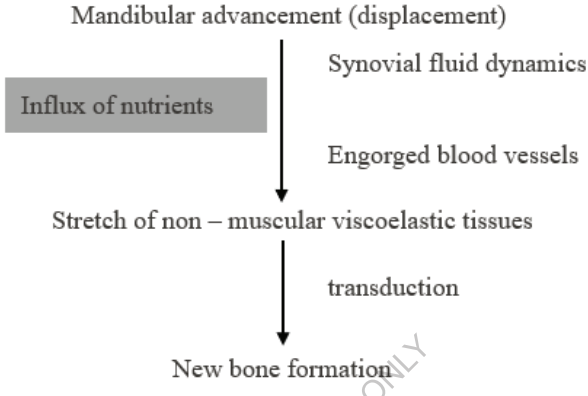
c) Functional matrix theory

what specifically affects the growth at the condylar head ?

A third hypothesis, the functional matrix theory, postulates the principal control of bone growth is not the bone itself, but rather the growth of soft tissues directly associated with it,[93-96] but there has been no explanation as to exactly how condylar growth would be stimulated. Thus, this theory's validity has been questioned.[87,97]

Extension of wolff's law

Growth relativity states that- "with orthopaedically displaced condyle, the bone architecture is influenced by the neuromusculature and the contiguous, nonmuscular, viscoelastic tissues anchored to the glenoid fossa and the altered dynamics of the fluids enveloping bone".



Flowchart-1

FOR AUTHOR USE ONLY

Viscoelastic changes : During orthopedic mandibular advancement, there is an influx of nutrients and other biodynamic factors into the region through the engorged blood vessels of the stretched retrodiskal tissues as, that feed on the fibrocartilage of the condyle. The expulsion of these factors occurs during reseating of the displaced condyles in the fossa during relapse. The result is a metabolic pump-like action of the retrodiskal tissues.[98]

Three growth stimuli

The 3 trigger switches for glenoid fossa growth can similarly initiate short-term condylar growth modifications. These are (Displacement + Viscoelasticity + Referred Force)

a) Displacement- significant glenoid fossa bone formation occurs during treatment that includes mandibular displacement.
b) Several direct viscoelastic connections- glenoid fossa modification is a result of the stretch forces of the retrodiskal tissues, capsule and altered flow of viscous synovium.
c) and transduction of forces or referral of forces- observations that glenoid fossa bone formation takes place a distance from the soft tissue attachment.

Light bulb analogy of the condylar growth and retention

To describe condyle-glenoid fossa growth modification, an analogy is made to a light bulb on a dimmer switch. The condyle illuminates in treatment, dims down in the retention period, to near base levels over the long-term.

When the condylar growth is continuously advanced, it lights up like a light bulb.

When the condyle is released from the anterior displacement, the reactivated muscle activity dims the light bulb and returns it close to normal growth activity. Its growth potential diminishes with age, whereas the glenoid fossa remodeling "lighting" potential lasts long into adulthood. The upper open coil in the box shows the potential of the anterior digastric muscle and other peri-mandibular connective tissues to reactivate and return the condyle back into the fossa once the advancement is released. The lower coil represents the shortened inferior LPM as shown in Figure-26.[99]

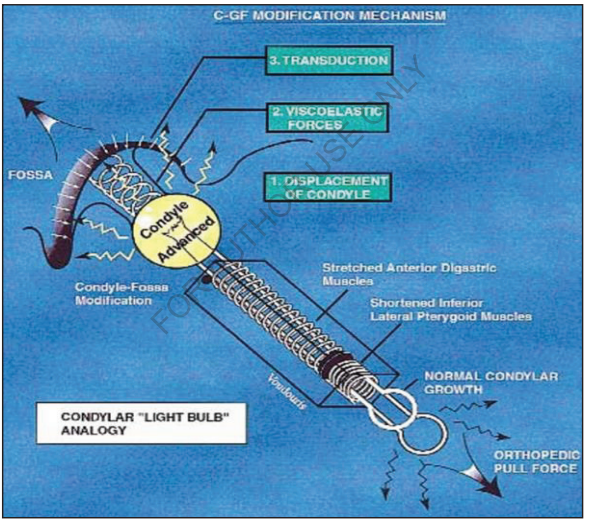


Fig 26. Light bulb analogy of condylar growth and retention. When the growing condyle is continuously advanced, it lights up like a light bulb on a dimmer switch.When the condyle is released from the anterior displacement, the reactivated muscle activity dims the light bulb and returns it close to normal growth activity. In the boxed area, the upper open coil shows the potential of the anterior digastric muscle and other perimandibular connective tissues to reactivate and return the condyle back into the fossa once the advancement is released.The lower coil in the box represents the shortened inferior LPM.The open coil above the yellow condylar light bulb represents the effects of the stretched retrodiskal tissues. (Taken from Voudouris JC, Kuftinec MM. Improved clinical use of Twin-block and Herbst as a result of radiating viscoelastic tissue forces on the condyle and fossa in treatment and long-term retention: growth relativity. Am J Orthod Dentofac Orthop 2000;117:247-66.)

CONCLUSION

The MCC is a secondary cartilage that in subadult individuals serves both as a site of growth and as a place of articulation. As such, it displays some functional characteristics of both a growth plate as well as an articular cartilage, but it differs from both in fundamental aspects of its development and structure throughout ontogeny.[13]

Clinical relevance

Condylar growth and adaptation are important in various clinical conditions. Mandibular morphology reflects condylar growth direction. The direction of condylar growth was found to be related to both mandibular rotation and overbite.

Vertical condylar growth was shown to occur in association with forward mandibular rotation and an overdevelopment of posterior facial height. Vertical condylar growth should not necessarily be considered a contraindication to treatment of deep overbite. Backward rotation usually occurred when condylar growth was in a sagittal direction as shown in Figure-27.

FOR AUTHOR USE ONLY

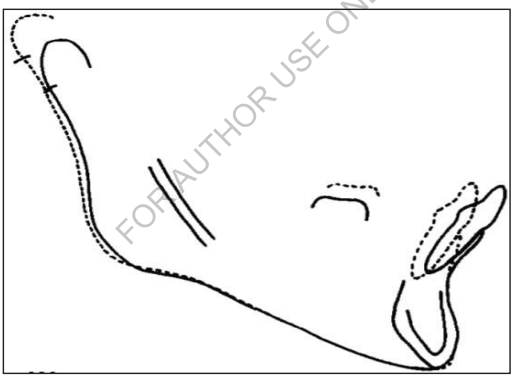

Fig 27. Facial growth with a more sagittal type of mandibular condylar growth (Taken from Levin RI. Treatment results with the Begg technique. Am J Orthod Dentofac Orthop 1977;72:239-260.)

Treatment of deep overbite differed for patients with vertical or sagittal condylar growth. In cases with sagittal condylar growth, the overbite was significantly smaller at the end of treatment and at the final examination. Therefore, it appears that deep overbite was treated more successfully when condylar growth was sagittal.

Patients with upward and forward growth of the mandibular condyle often have reduced anterior face height; if they develop a malocclusion; it is nearly always characterized by a deep bite.

In more extreme cases of upward and forward growth of the condyle a class II division 2 malocclusion in combination with a skeletal deep bite is common.

Patients with 'long face syndrome,' and a pronounced increase in lower face height in contrast have a more posteriorly directed growth pattern of the mandibular condyle as shown in Figure-28.[100]

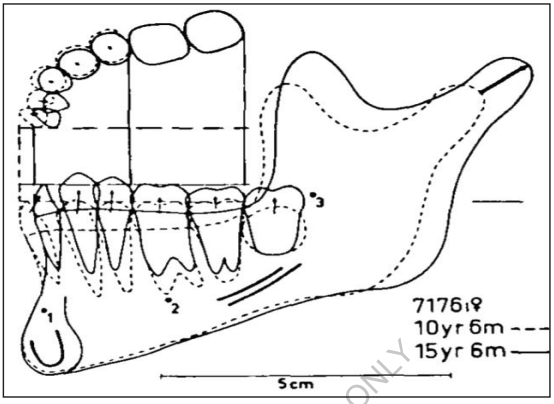

Fig 28. The condylar growth direction is mainly posterior. The direction of the eruption of the teeth is almost vertical.(Taken from Bjork A. Variations in the growth pattern of the human mandible: longitudinal cephalometric study by the implant method. J Dent Res 1963;400-411.)

FOR AUTHOR USE ONLY

Growth rotations and vertical malocclusion

The changes related to facial growth illustrated with these two extreme growth patterns are due not only to differences in condylar growth direction, but are also the result of differences in anterior facial height (AFH) and posterior facial height (PFH) development. These differences in height development lead to rotational growth or positional changes of the mandible that greatly influence the position of the chin. The factors that determine the increase in AFH are the eruption of the maxillary and mandibular posterior teeth and the amount of sutural lowering of the maxilla. PFH on the other hand is determined by the lowering of the temporomandibular fossae and condylar growth.[101]

When vertical condylar growth exceeds dentoalveolar growth, i.e. eruption of the teeth in the jaws, forward rotation of the mandible occurs. In contrast, if dentoalveolar growth is greater than vertical condylar growth, the resulting change in mandibular position is backward or posterior rotation of the mandible. The two extreme mandibular growth patterns also show differences with respect to the amount of effective vertical condylar growth.

Patients with an anterior condylar growth pattern usually have a greater amount of vertical growth than patients with posteriorly directed growth, a factor that further accentuates the differences. Patients with posterior condylar growth often have similar amounts of AFH and PFH increase, where the mandible translates during growth without rotation.

Hemimandibular hyperplasia causes an enlargement of the condyle, the ramus and the body of the mandible including the alveolar process without an accompanying marked chin deviation. While articular cartilage and subchondral bone are separated in the healthy condyle, in hemimandibular hyperplasia, no distinction can be made histologically between these tissues.

Hemimandibular elongation is another abnormal growth condition that induces lengthening of the mandibular condyle, ramus, and body, and causes chin deviation. No histological abnormalities are detected within the condyle.

The use of functional appliances results in a small but statistically significant increase of mandibular length. Functional appliances constructed on the principles of 'jumping the bite', such as the Herbst appliance and the twin-block are more effective in modifying mandibular growth than passive appliances, such as the Andresen activator and its variants. This might be the combined result of remodelling of both the condyle and the fossa.[102] In short, mandibular condyle is highly adaptive and its growth direction and magnitude can be modified. Following a bilateral sagittal split osteotomy, mandibular body is moved into a new maxillomandibular relationship, during which meticulous attention is paid keeping the condyle–fossa relationship unchanged.[103]

FOR AUTHOR USE ONLY

Variation in growth intensity is an additional factor that not only induces change in the developing occlusion, but also affects the length and outcome of orthodontic treatment. During periods of low condylar growth intensity such as the juvenile period or the prepubertal growth minimum, intensity may be as little as 1-2mm per year in the condyles. Orthodontic treatment during these periods presents the orthodontist with significant clinical problems. It is difficult during these periods in some patients to obtain sufficient skeletal change and treatment can become protracted. Fortunately, some young patients are more actively growing during the juvenile period and skeletal correction can be achieved over a more reasonable period of time.[100]

FOR AUTHOR USE ONLY

This book is a compilation of the craniofacial muscles, their embryogenesis and morphogenesis. The detailed anatomy of the craniofacial muscles and their role in the growth and development of the craniofacial complex. The role of the masticatory muscles in different facial types also has been a debate for long i.e. genetics versus function and an elaborate discussion with evidence-based data has been included in this book. Muscles have shown to play a very active growth in the formation, shape and extent of growth of the bones of the craniofacial complex.

Introduction

Unraveling the complex tissue interactions essential to generate structural and functional diversity present among craniofacial muscles is very challenging. There are 60 distinct skeletal muscles in craniofacial region the head that control food intake, facial expression and eye movement. The development of these muscles is closely coordinated with other craniofacial tissues. The head musculature is known to originate from the cranial paraxial mesoderm (CPM) located anterior to the somites., and lacks any overt signs of segmentation. The CPM cells move into the branchial arches which eventually give rise to the facial structures. The regulation of head muscle patterning and differentiation by signals from adjacent tissues has been extensively explored in recent past.[1] The organization of craniofacial muscles is highly conserved, yet they are the most diverse musculoskeletal structures present in vertebrates. Skeletal muscles throughout the body originate within paraxial mesoderm. In the head of amniote embryos, this tissue forms and remains as mesenchymal population, devoid of either epithelial compartments or overt segmentation. Following gastrulation, neural and surface ectodermal epithelia over lay the cephalic paraxial mesoderm and pharyngeal endoderm below it. Neural crest cells subsequently spread over its superficial surface. Identifiable compartments such as myotomes and sclerotomes are not evident, still the cell types generated within head paraxial me-soderm are identical to those present in trunk somite.

FOR AUTHOR USE ONLY

At various axial levels, the differentiation of skeletal muscle require a consortium of transducting signals, whose regulatory influences establish spatially and temporally diverse myogenic populations.[2]

Various tissues adjacent to craniofacial myogenic mesoderm are unique to the head (neural crest–derived mesenchymal cells and pharyngeal endoderm) and segment-specific. Each of these adjacent tissues needs to be vetted for its role in head myoblast differentiation and morphogenesis. Having neighboring mesodermal cells being mesenchymal instead of epithelial creates opportunities for various different signaling and signal transduction strategies. Most craniofacial muscle primordial move from their sites of differentiation within the paraxial mesoderm into peripheral locations e.g., muscles that rotate or elevate the skull, move in conjunction with their connective tissue precursorsand most venture into novel surroundings. During various excursions, which may precede or follow overt differentiation of myocytes (cells expressing skeletal muscle specific markers), head muscles become surrounded by and infused with neural crest cells which form endo ,peri and epimysial compartments. The combination of crest and myogenic mesoderm cells coincides with the elongation and alignment of myocytes and immediately precedes both the segregation of individual muscles from common progenitor cells and the formation ofintramuscular vascular channels.

FOR AUTHOR USE ONLY

Classification Of Craniofacial Muscles

The head muscles are generally classified according to their anatomical location within the head:

They can also be classified as four distinct populations [3]

i. extra-ocular

ii. branchial

iii. laryngoglossal,

iv. axial

Axial includes epaxial and hypaxial muscle groups that elevate, depress, and rotate the head. Terrestrial vertebrates have superficial muscles that are part of a constrictor colli system which circumscribe the caudal part of the head and extend underneath the jaw, and function to provide ventral muscle tone and help in swallowing. Mammals set of superficial facial muscles that allow fine movements of lips, eyelids, and cheek, nose and with specialized pharyngeal constrictors.

FOR AUTHOR USE ONLY

A] Extra-Ocular Muscles (EOMs)

The function of EOMs is to move and maintain the rotational stability of the eye in birds. The basic pattern of the six EOMs is common among all vertebrate classes, with various evolutionary adaptations. In early gnathosomes, vertical orientation of the lateral rectus is seen instead of the horizontal alignment seen in most vertebrates. In caecilian amphibians, the size of the eyes is reduced and varioous EOMs have been modified as protractor and retractors of an external appendage called the tentacle. A functional EOM adaptation is seen in marlins,

sailfish, and swordfish. The dorsal rectus is sufficiently enlarged and modified asa tissue capable of warming the brain and eye 14°C above normal temperatures. [3] Amniote EOMs which are established during primary myogenesis are compartmentalized into global and superficial orbital domains[4]. The distal attachments of individual domain are different thus allowing the global domain to initiate eye movements, while the orbital acts via the connective tissue pulleys as an elastic loading system, maintaining the rotational stability as the eyes move along the horizontal and vertical planes.[3]

B] Branchial Muscles

Branchial muscles are those associated with maxilla, mandible, hyoid, and caudal branchial skeletal structures and their homologues. These muscles have evolved from an iterative set of serially homologous gill muscles, which along with gill skeletal elements constituted the branchiomeric apparatus.[5] However, recent evidence suggests that the first branchial arch mig have arisen with unique structural and molecular attributes and not evolved from gill-supporting ancestor [3] Axons innervating branchial muscles extend from motor neurons which become segregated in lateral regions of the brainstem, distinct from EOM and somatic motor nuclei.[6] As the terrestrial vertebrates evolved and there was loss of gill- supporting skeletal elements and the muscles within each arch underwent substantial modifications.

FOR AUTHOR USE ONLY

The embryonic origins of suprahyoid muscles are diverse, including mylohyoid arch and digastricus, stylohyoid, plus occipital somites (geniohyoid). Muscles

associated with external ear movement and facial expression are unique to mammals. They are derived from late-differentiating second branchial arch myoblasts that segregate to periauricular, periorbital, and perioral regions. [3]

C] Tongue and Intrinsic Laryngeal Muscles

Glossal and laryngeal structures are relatively recent evolutionary adaptations of the craniofacial musculoskeleton.[7] However, the muscles associated with these structures have a more extended ancestry. Analyses of pax3/7 gene expression in lamprey embryos identify a population of hypobranchial myoblasts that originate from the lateral borders of rostral somites and migrate beneath pharyngeal structures.[8] Comparable myoblasts in fishes attach ventral gill elements to the coracoids bone of the pectoral girdle.[9] In amphibians and amniotes, migratory myoblasts arising from occipital somites form a condensed mesenchymal band, the hypoglossal cord that elongates and similarly brings myoblasts ventral to pharynx, where they form both intrinsic and most extrinsic tongue muscles and intrinsic laryngeal muscles.[10]

FOR AUTHOR USE ONLY

Since these muscles arise at the boundary of trunk and head, there has been much conjecture about which category best suits these wandering myoblasts. Early hypotheses that tongue muscles are modified gill (branchial arch) muscles isdisappeared by the finding that their innervation (cranial nerve XII) is fromneurons located in somatic rather than branchial motor nuclei.[11] Also, some tongue muscles are spared in transgenic mice null for Tbx1, a transcription factor that is required for differentiation of all branchial muscles.[12] They are probably

best described as hybrids, originating from somites but completing their development within craniofacial microenvironments.

D] Axial Muscles

Muscles associated with postural stabilization and movements of the head are multisegmental and all arise from medio-dorsal and latero-ventral domains of occipital and cervical somites.[13] These muscles are organized as epaxial (dorsal tothe transverse process of each vertebra) and hypaxial (ventral to the transverse process) similar to other trunk muscles. Among the hypaxial are the infrahyoid muscles, which in mammals include the omo-, sterno-, and thryohyoid muscles. These function to lower the root of the tongue as well as larynx and, and are innervated by hypoglossal (XII) and cervical nerves.

Embryonic origins and organization of head mesoderm

e cascade of events will be explained according to following sequence1 Head Cavities and Pre-Otic "Somites"

2 Prechordal Mesoderm

3 Paraxial Mesoderm

4 Regionalization of the head mesoderm

FOR AUTHOR USE ONLY

1] Head Cavities and Pre-Otic "Somites"

Balfour (1877) described a series of three segmentally arranged, epithelial-lined condensations rostral to the otic vesicle in shark embryos.[14,15] At early stages, these retain connections with the coelomic cavity. These become isolated during

expansion of pharyngeal pouches and visceral clefts. The dorsomedial layer surrounding each head cavity forms a myotome-like epithelium that becomes associated with an EOM-innervating cranial nerve. Gilbert (1957) identified mesenchymal condensations in early cat and human embryos that included primordia of extraocular muscles and within which small epithelial clusters formed [16]. Jacob and colleagues described small, paired premandibular cavities in chick embryos. [17]

2] Prechordal Mesoderm

Head mesoderm is formed at the beginning of gastrulation and is in position by mid gastrulation stages. In the median plane, it includes prechordal mesoderm located beneath the rostral neural plate, followed caudally by the notochord. Prechordal mesoderm is contiguous laterally with paraxial mesoderm which extends caudally to the first somite. [18]

Prechordal mesoderm is generated from progenitors located in the rostral margin of the elongating primitive streak (avian) and is often indistinguishable from the overlying neuroepithelial and underlying endodermal layers.[19] Hedgehog and nodal signals from these mesodermal cells are necessary for the regional specification of the rostral neural plate and also for the bilateralization of prosencephalic structures. [20,3]

FOR AUTHOR USE ONLY

Transplantation and retroviral mapping studies show that these cells contribute to the formation of the dorsal, ventral, and medial rectus and ventral oblique muscles, all of which are innervated by the oculomotor (IIIrd) nerve. [21,22]

3] Paraxial Mesoderm

Paraxial mesoderm generated from the primitive node and streak beginning at the onset of gastrulation, and most of the head mesoderm is formed by the time the streak reaches its maximum length. The head paraxial mesoderm appears as a rapidly generated population without spatially separable progenitors. [23]

4] Regionalization of the head mesoderm

The exact molecular nature of the CPM and SpM , remains unclear. Recent gene expression analyses in avian models have begun to reveal the molecular milieu of head muscle progenitors in St. 8, St. 10, St. 16 and St. 20 and 24 chick embryos. [24,25,26,27] Pitx2, Tcf21 (capsulin), Msc (MyoR), Twist, Alx4, and Tbx1 genes are shown to be expressed in the head mesoderm; Alx4, Tbx1, Cyp26C1, and Twist are expressed in the CPM In St. 8 chick embryos, the SpM is found to express, Isl1, Nkx2.5, Fgf10, and Tbx20, a set of second heart field markers in agreement with the cardiogenic potential of these cells. [24] There is considerable overlap in the expression of head muscle markers e.g., Myf5, Tcf21 (capsulin), Msc (MyoR), Tbx1, Pitx2 and cardiac lineage markers (e.g., Islet1 and Nkx2.5) in the CPM and SpM.[24] Taken together, these studies have begun to delineate the molecular regionalization of the headmesoderm continuum in these fields along the medial– lateral/dorsal–ventral axes.

Most head paraxial mesoderm remains mesenchymal, and the population appears homogeneous from the optic vesicles to the hindbrain, where the first somite

FOR AUTHOR USE ONLY

forms either close to or several rhombomere lengths caudal to the otic primordium. Fgf8, retinoic acid, and Wnt signaling integrated with periodic waves of Notch pathway related genes such as hairy1 and 2 and lunatic fringe ordinate the formation of somites.

In a series of SEM examinations in amphibians, reptiles, chicks and mammals; the superficial and deep surfaces of head mesoderm were found to be demarcated by a series of shallow transverse grooves, between which the mesenchymal cells showed a biased circular orientation named somitomeres, represent vestiges of an evolutionarily earlier condition in which head mesoderm was fully segmented.[28,29,30] However they arrest before epithelialization and thus lack any apparent separations.

Comparative analyses show that the position of specific somitomeres relative to other axial structures, specifically mid- and hindbrain segments, is not constant among embryos of the different vertebrate classes thus far examined.

An important early distinction among the progenitors for each of these lineages is their pattern of movement. Chondrogenic mesoderm cells are essentially stationary, changing location by differential expansion and growth of prechondrogenic and early cartilage cell populations, analogous to the processes underlying vertebra and rib formation.[31] Osteogenic precursors of intramembranous bone originate deep and medially within head paraxial mesoderm. These cells move dorsally around the brain, occupying sites where in the chick embryo the roofing part of the frontal and the parietal bones will form.In mice, the entire frontal is of neural crest origin.

FOR AUTHOR USE ONLY

Early accounts of head muscle origins in a wide range of vertebrate embryos described the initial locations of many myogenic condensations within branchial arches, and concluded that myoblasts originate within this lateral mesoderm. [32] With the availability of progenitor cell–labeling methods, especially in avian and murine embryos it was discovered that all head myoblasts arise in paraxial mesoderm, often far removed from the locations at which overt condensation and terminal differentiation will occur. [22,33]

Progenitors of head skeletal muscles are organized either as individual muscle primordia, e.g., most EOMs, or as cohorts of myoblasts that will populate specific branchial arches and later segregate into several muscles. Branchial muscle primordial are located superficially within head paraxial mesoderm. As such they are initially in contact with overlying surface ectoderm and are more distant from the notochord and pharyngeal endoderm. EOM primordia tend to be closer to the midbrain and hindbrain than are branchial myoblasts. The precursors of the lateral rectus, especially, are located ventromedially, tucked between the trigeminal ganglion and the ventrolateral margin of rhombomere 2. [34]

FOR AUTHOR USE ONLY

Molecular aspect of Axial Muscle Differentiation

The core myogenic network consists of the basic helix-loop-helix (bHLH) myogenic regulatory factors Myf5, Mrf4 (Myf6 – Mouse Genome Informatics), Myod (Myod1 – Mouse Genome Informatics) and myogenin, which determine muscle identity and/or promote muscle differentiation.[35] These factors have been

'redeployed' during evolution to build the new head muscles. However, their roles differ in EOM versus PA skeletal muscle founder cells. [36]

A] Myf5

Myf5 expression in the cervical and occipital somites is regulated by a unique promoter, and loss of gene function (e.g., six1/4, pax3, CREB, or shh) has been shown to differentially affect myogenic differentiation in this region.[37] These differences may be the result of the combinatorial Hox code along the body axis, changes in Notch signaling in the mesoderm underlying the developing hindbrain.

[38] Heterogeneity between the different head and trunk muscles is further exemplified by analyses of the myf5 regulatory sites. Distinct enhancers regulate myf5 expression both temporally and spatially within the developing embryo in a combinatorial and co-operative fashion. Myf5 expression within the craniofacial musculature is also differentially controlled. [39] Each of the several branchial arch muscle enhancers will drive myf5 expression, but loss of function studies suggest these regulatory sites operate as part of an integrated modular controlling network. [36]

FOR AUTHOR USE ONLY

B] MyoD

The myoD enhancer controls the onset of myoD expression, and regulates myoD expression in differentiating myoblasts. [40] Even within the short core enhancer, myoD expression in the somites versus the limb and branchial arches is

differentially regulated, again indicating that the signaling networks regulating the onset of myogenesis are not mimicked throughout the embryo.

C] Pax3 and Pax7

In somitic muscle founders, Pax3 and Pax7, paired-homeodomain genes, act genetically upstream of Myod and they are likely to activate Myod expression by binding to its regulatory sequences. [41,42] Pax3 expression is absent in head muscle stem/progenitors. [43] Furthermore, in Pax3:Myf5:(Mrf4) mutant embryos (in which embryonic Mrf4 expression is perturbed in cis by disruption of the Myf5 locus) trunk muscles fail to form whereas most head muscles develop. Some head muscles or their precursors express several regulatory genes, including tbx1 , engrailed, and capsulin (epicardin,POD1) that are not typically part of the axial myogenic repertoire. Inactivation of Tbx1 in mice or zebra fish (van gogh) causes severe reduction of branchial arch muscles sparing only a small number of myoR and capsulin-expressing muscle cells in the mandibular prominence. [12] These survivors indicate the presence of heterogeneity among branchial arches either in the myogenic populations or the surrounding signaling environments MyoR, was originally identified as a myogenic repressor and it is possible that this upregulation is linked to the first arch myogenic defects in the tbx1 mutants. [36]

FOR AUTHOR USE ONLY

D] Pitx2 and Tbx1

Pituitary homeobox 2 (Pitx2) is a bicoid-related homeodomain transcription factor expressed widely in the head of mouse embryos, including within the CM and the

pharyngeal ectoderm. It plays a key role in specifying EOMs, which are missing in Pitx2-null mice as well as is a key regulator of PA muscle development. [44] Pitx2 is expressed in trunk muscle progenitors has shown to act downstream of Pax3 in somitic myogenesis. [45] Pitx2 binds directly to the promoters of Myf5 and Myod., in EOMs.[45] The T-box gene Tbx1 is critical for PA muscle development but is not required for trunk myogenesis. This transcription factor specifies PA, but not EOM, muscle founder cells. [43] In Tbx1- null mouse mutants, first PA myogenesis is impaired, and the posterior arches themselves are absent, highlighting the additional role that Tbx1 has in ectoderm and endoderm in PA development. A monolateral ablation of skeletal muscles is observed in Tbx1-nullmutants, indiating that an all-or-nothing mechanism for the generation of muscle founder cells. [46]

Tbx1 and Pitx2 cross-regulate each other and activate the same target genes explaining that PA myogenesis is observed occasionally in Tbx1:Myf5 double mutant mice [43]

Pitx2 and Tbx1 expression is not restricted to the mesoderm but instead has a much broader expression pattern in cells adjacent to EOM and PA mesoderm. In humans, PITX2 mutations cause Rieger syndrome, which is associated with ocular as well as cardiac anomalies and dental hypoplasia. [47] Human TBX1 mutations contribute to the anomalies seen in DiGeorge syndrome, which is characterised by cardiovascular and craniofacial defects together with PA muscle weakness and skeletal muscle hypotonia. Therefore, these genes could act both

FOR AUTHOR USE ONLY

cell autonomously, as well as non-cell autonomously, to affect muscle development.

E] Musculin and Tcf21

Msc (musculin; also known as MyoR) is expressed in head and body muscles, andTcf21 (also known as capsulin), are bHLH transcription factors which are considered to act as repressors. They play key roles in the PA, but are not expressed in the EOM founder cells. Mouse embryos with mutations in both thesegenes fail to develop a subset of first arch-derived jaw muscles (the masseter, pterygoid and temporalis muscles. [48] The link between these transcription factors and the MRFs has not been clearly established.

F] Others

Other regulatory genes common to subsets of both head and trunk muscles are the transcription factors, myoR, meox1, six1 and -4, barx2, the homeobox transcription factor pitx2, and the c-Met ligand HGF (hepatocyte growth factor).

[49] The order of expression of these genes is often dissimilar between head and trunk. Loss of function studies of these genes typically result in less severe disruption of head myogenesis compared with the trunk. Inactivation of the homeobox gene, six1, affects the diaphragm and abdominal wall muscles togetherwith a subset of limb and tongue muscles but leaves epaxial and other head muscles relatively unaffected. In the double Six1/Six4 knockouts, these defects are exacerbated. Moreover, the defects now extend to the head muscles, delaying

FOR AUTHOR USE ONLY

extraocular but not branchial arch myogenesis. [37] Myogenic lesions following lossof pitx2 function in mice are found only in the extraocular muscles, which fail to condense. In this initial study, it was not evident whether the muscle dysgenesis resulted from an intrinsic defect in the developing myoblasts or was secondary to loss of pitx2 expression in the periocular mesenchyme. Our own studies have suggested that pitx2 regulates myogenic cell number cell autonomously, consistent with its ability to regulate cell proliferation in the satellite cell line, C2C12. This has been confirmed recently by the demonstration that gene- inactivation of pitx2 in the periocular cranial neural crest cell does not affect the early differentiation of eye muscles. Many genes essential to the formation of subsets of trunk muscles are either not expressed in head muscles or only in very limited circumstances. [36]

Mechanisms Of Craniofacial Myogenesis

The preceding sections have emphasized unique attributes of developing craniofacial muscles, both individually and as groups, and revealed significant disparities between head and trunk myogenic populations. Relatively little isknown of the mechanisms underlying this diversity. Extrapolating from analyses of trunk myogenesis, tissue interactions that control development of primary head myofibers will involve multiple surrounding tissues, including other members of the paraxial mesoderm community. These interactions will require a consortium of molecular signals to produce a combination of positive inductive and inhibitorysignals. [50]

FOR AUTHOR USE ONLY

Cranial myogenic mesoderm is variably proximate to a number of tissues e.g., the neural tube, notochord, pharyngeal endoderm, surface ectoderm, and neural crest cells, each of which harbors cells simultaneously making localized commitments to different lineages. For example, within surface ectoderm overlying several head muscle precursors are sites at which neurogenic placodes for trigeminal, facial and glossopharyngeal sensory ganglia are established. The initial specification of these placodal fields are determined by combinatorial signaling involving members of the Wnt, Fgf, and Bmp families that are produced by underlying paraxial mesoderm: Bmps and Wnts are inhibitory for placodal specification while FGFs are inductive.[3] Additional region-specific signaling scenarios have been identified within the paraxial mesoderm underlying the otic placode. Here the mesoderm produces Fgf3, Fgf19, and Tbx1. Were as cranial mesoderm expresses Wnt and Bmp antagonists and surface ectoderm depress the ability of mesoderm cells to initiate (or elevate) expression of Myf5.[51] Normally, the neural crest population expands over the precursors of 1st branchial arch muscles, effectively separating myogenic cells from this overlying source of inhibition. Furthermore, crest cells express the Wnt antagonist Frzb, and the Bmp antagonists noggin and gremlin.

Wnt1 exhibits a dynamic expression pattern in the midbrain, and except for the dorsal midline is not expressed in the metencephalon. It can be envisaged that local areas of lesser Wnt release might correspond to specific myogenic foci within paraxial mesoderm.Wnt3a expression is confined to the caudal hindbrain

FOR AUTHOR USE ONLY

(myelencephalon),while wnt5a transcripts are present in the rostral hindbrain(metencephalon); wnt7a is absent from the ventral midbrain

Shh is released by the notochord and ventral neural tube in the head, and also by bands of pharyngeal endoderm cells. Despite the key role of Shh in the maintenance of epaxial trunk muscles, cranial mesoderm explants failed to demonstrate any physiological role for Shh in the initial regulation of myogenic differentiation, to the onset of myogenesis. [52] This lack of Shh responsiveness may be augmented by the co-expression of Bmp7 from the floor of the diencephalon and midbrain and also the notochord. [53]

Finally, we must consider intra-mesodermal interactions, which in somites are essential to specify both the medial and lateral myotomal regions.

Morphogenesis of Head Muscles

Muscle morphogenesis encompasses three integrated processes:

i. the relocation of muscle precursors from their site of origin to the location of their terminal differentiation,

ii. the assembly and alignment of primary myotubes

iii. the segregation of individual muscles with appropriate attachments to surrounding connective tissues. Migrating myoblasts emigrate from the lateral myotomes at specific, restricted sites (occipital, cervical, brachial, lumbosacral). These cells are pax3-dependent, and express the transcription factors lbx1, paraxis, and six1. [54,55] Lbx1 and the c- Met as well as CXCR4 receptors are essential for their emigrations. Migrators

from each of the several occipital somites contribute to all intrinsic and extrinsic tongue muscles; therefore, the spatial organization for individual muscles occurs either en route or upon the arrival of myoblasts at their final destination.

Neural crest cells en route to each arch overlie presumptive branchial muscle primordia, and both of these mesenchymal populations shift ventrally in concert and during this process, crest cells circumscribe but do not penetrate the condensed cord of muscle precursors. Shortly thereafter, motor axons contact and enter the myogenic cord. [56]

EOM primordia achieve their terminal locations by a combination of population expansion, extended, multidirectional movements, and changes in the relative position and orientation of the eye due to cranial flexure move en masse into neural crest– occupied periocular territories. [57] Reciprocal interactions between the eye and EOMs are necessary for both differentiation of the retina and formation of secondary motubes. [58,3]

From its origin lateral to the midbrain, the dorsal oblique primordium shifts rostrally right angle around the equatorial margin of the optic cup. These movements distance it from its initial neighbor, the lateral rectus precursor, and, remarkably, cause it to pass the ventral oblique primordium that is moving in the opposite direction. [3] These translocations bring each EOM primordium into periocular mesenchyme derived from neural crest cells. The crest-mesoderm interface is undetectable in normal embryos. [3]

Borue and Noden, (2004) have proposed a passive displacement model based on changes in the contour of the neural crest: mesoderm interface. [59] Following

FOR AUTHOR USE ONLY

transplantation of trunk paraxial mesoderm into sites normally occupied by lateral rectus and some dorsal oblique progenitors, it was found that a discrete band of small muscles and individual myotubes distributed along the pathway traversed by the dorsal oblique muscle. This suggests that the dorsal oblique is not a moving island, but rather is at the tip of a finger-like projection of mesoderm that penetrates and interdigitates with comparable but oppositely oriented projections of neural crest cells. Normally, periocular crest cells would encircle and isolate the myogenic tip, perhaps similar to the process by which branchial crest cells circumscribe the myogenic core within each arch. However, this final step is blocked when ectopic trunk mesoderm cells are present, as has been previously described.

The separation of individual muscles and their formation of attachments with branchial skeletal and connective tissues is dependent upon positional cues provided by surrounding connective tissues. Manipulation of branchial arch crest populations, either by transplantation or genetic alteration; results in a patterned alteration in the organization of muscles that mimics the changes in skeletal organization. [60,61] Despite the regional differences in pre-tendon signals, there must be extensive overlap in the consortium of signals controlling muscle morphogenesis in the head and trunk, as transplanted mesoderms cells are fully able to respond to cues in either location.

FOR AUTHOR USE ONLY

The morphogenesis of many head muscles is a prolonged process during which some muscle cells form attachments far from their original branchial confinements. Koentges and Lumsden (1996) showed that neural crest and

myogenic populations maintain their original close association even when they exit the arch in which they originated. [62] These establish attachments with skeletalelements in adjacent branchial arches and also with the mesodermal cartilages in laryngeal, neurocranial, and shoulder regions. This congruency between myogenic and crest-derived connective tissue precursors is not established until after crest cells have fully occupied the branchial arches and circumscribed each muscle plate. [22] Later remodeling of branchial muscle attachment sites occur independent of the neural crest. The mechanisms by which individual muscles detach and then reattach to separate skeletal structures are not known. The rule of congruence between myoblasts and neural crest cells also does not apply to the muscles associated with facial expression.

While it is presumed that periocular neural crest cells play a similar role in EOM morphogenesis, direct evidence is lacking. Gross disruptions of either eye development.

The term “cardio-craniofacial morphogenetic field” reflects the intimate developmental and cellular relationship between the head, face, and heart, which is manifested in numerous cardiac and craniofacial birth defects. [3]

The Masseter Muscle

The masseter muscle is one of the muscles of mastication that has been investigated extensively in humans. This has been due to its close relation to the mandible and its ease of accessibility. It is composed of two portions, the deepand the superficial bellies

a) The superficial belly arises from the zygomatic process of the maxilla as well as the zygomatic arch and runs downwards in a diagonal direction to be inserted onto the lower lateral border of the ramus of the mandible and the gonial angle

b) The deep belly arises from the medial surface of the zygomatic arch and runs downwards and backwards to be inserted onto the upper half of the ramus of the mandible.

Masseter muscle fibre types

Several methods have been employed to classify muscle fibres (e.g. histochemicaltyp I, IIA and IIB fibres). However, with the evolution of science, new classifications have been implemented using mainly molecular genetic techniques. This scheme includes the transcriptome (gene expression) and proteomic (protein) expression properties of the myosin heavy chain (MyHC) proteins. The human masseter muscle has been reported to have various MyHC proteins encoded by various myosin heavy chain genes (MYH)

FOR AUTHOR USE ONLY

Temporalis Muscle

The temporalis muscle is a very important muscle with respect to mastication, reducing temporomandibular dislocations, and as a landmark distally foridentifying the long buccal nerve. The Latin name is musculus temporalis. It is considered one of the four main muscles of mastication and is crucial to the elevation and retraction of the mandible. The temporalis originates from the temporal lines of the parietal bone of the skull, whose fibers converge and descend into a tendon that passes through the gap formed from the zygomatic archand the side of the skull. The fibers then insert onto the medial surface, the apex, anterior, and posterior borders of the coronoid process, and further down onto the anterior border of the ramus of the mandible. The muscle can be subdivided into the anterior (vertical) and posterior (horizontal) fibers, whose actions are to elevate and retract the mandible back into a resting position after movement. The temporalis can be further subdivided into a deep and superficial portion, such that the deep portion can be considered a separate muscle, the sphenomandibularis muscle. The overwhelming majority of the textbooks, atlases, and specialty dentaltexts described simply a “coronoid process attachment” and/or an “attachment to the anterior border of the ramus of the mandible.” A few further described the distal attachment “down as far as posterior to the third molar.” Although all these descriptions of the distal attachment of the temporalis tendon are partially correct, they are inconsistent with each other and incomplete with respect to the evidence found from the dissections of actual cadavers. The osseous nomenclature of its distal attachment is also unclear. The region described as “posterior to the third

FOR AUTHOR USE ONLY

molar" is often referred to as the retromolar triangle or fossa. Cadavers reveal the distal attachment of the temporalis tendon bifurcating before attaching to the medial and lateral borders of the retromolar fossa, which is located posterior tothe last molar of the mandible. This description is more accurate with respect to the observations from the cadaver dissections. The temporalis tendon also attaches to the coronoid process and to the anterior border of the ramus of the mandible. The bifurcation of the distal attachment might impart a better balance between the broad origin attachment of the temporalis and the narrow insertion of the tendon because the increased number of attachmentmsites can better counterbalance the forces generated by the muscle.

Medial Pterygoid

The Medial pterygoid muscle in quadrangular in shape and has deep and superficial head. The deep head is attached above to the medial surface of the lateral plate of the pterigoid process and the associated surface of the pyramidal process of the palatine bone and descends obliquely downwards ,medial to the sphenomandibular ligament , to attach to mandible near the angle of mandible;The superficial head originates from the tuberosity of the maxilla and adjacent pyramidal process of the palatine bone and joins with the deep head to insert on the mandible The medial pterygoid elevates the mandible. Because it passes obliquely backwards to insert into the mandible, it also assists the lateral

FOR AUTHOR USE ONLY

pterygoid muscle in protruding the lower jaw. The medial pterygoid is innervated by the nerve to medial pterygoid from mandibular nerve.

Lateral Pterygoid

The human lateral pterygoid muscle plays an important role in the control of jaw movements. It consists of an upper or superior head (SHLP) and a lower or inferior head (IHLP). The lateral pterygoid is a thick triangular muscle and likethe medial pterygoid the muscle has two heads has two heads. The upper head originates from the roof of the infratemporal fossa (inferior surface of them greater wing of the sphenoid and the infratemporal crest) lateral to the foramen ovale and foramen spinosum. The lower head is larger than the upper head and originates from the lateral surface of the lateral plateof the pterigoid process and the inferior pat insinuates itself between the cranial attachments of the two heads of medial pterygoid. The fibres from both the heads of the pterygoid muscle converge to insert into the pterygoid fovea of neck of mandible and into capsule that are attached internally to articular disc. Unlike medial pterygoid muscle whose fibres tend to be oriented vertically those of lateral pterygoid muscle are oriented almost horizontally. As a result when lateral pterygoid contracts it pulls the articular tubercle and therefore the major protuder of lower jaw. The lateral pterygoid is innervated by nerve to lateral pterygoid froms the mandibular nerve. When lateral and medial pterygoids contract on only one side,the chin moves to the opposite side when opposite movements of the two temporomandibular joints are coordinated a chewing movement results. Contrary to previous anatomical

FOR AUTHOR USE ONLY

views that the SHLP inserts into the temporomandibular disk with the IHLP inserting into the condyle, the current view is that the IHLP inserts into the condylar neck and capsule, and the SHLP has a complex insertion into the condyle and the disk-capsule complex. The classical description of the normal function of the lateral pterygoid muscle is that the IHLP is active on jaw-opening, jaw protrusion, and contralateral jaw movements, and that the SHLP is active on jaw-closing, jaw retrusion, and ipsilateral jaw movements. Both heads are therefore said to have a reciprocal pattern of activity. One of the anatomic features of the LP that is unique to the jaw motor system is its muscle fiber architecture, which allows a major vector component of the total force output from the muscle to be generated in the horizontal plane; the LP is therefore ideally suited to generating horizontal jaw movements. Many investigators have studied LP anatomy; the muscle consists of an upper or superior head (SHLP) and a lower or inferior head (IHLP). While the IHLP inserts into the condylar neck and capsule, the SHLP has a complex insertion into the condyle and the disk-capsule complex. Within the SHLP and IHLP, there is a marked convergence of muscle fibers onto a small insertion site on the condylar fovea, capsule, and disc from a broad origin at the roof of the infratemporal fossa and lateral pterygoid plate. This marked change in fiber alignment from the uppermost to the lowermost muscle fibers, and from the medial to the lateral side of the muscle provides the opportunity for a range of force vectors capable of moving the condyle at the appropriate rate, and for the appropriate range and direction to effect the desired horizontal jaw movement.

Introduction

As long ago as 1955, Schottstaedt et al. described the feasibility of complete muscle transposition to restore function or to compensate for paralysed muscles. They transposed the sternomastoid muscles to function as masseter muscles in humans and also used the sternomastoids to replace the orbicularis otis muscles when the 5 th and 7 th cranial nerves were damaged. Several years later, Hamacher (1969) and Dingman (1969) also performed a muscle transposition so that the sternomastoids functioned as masseters. Eschler (1969) described a technique for transposing the masseters in human infants with the Pierre Robin syndrome, which consisted of detaching the masseter insertion from the angle of the mandible and repositioning it onto the posterior border of the ascending ramus. Eschler (1969) claimed that within three weeks his patients were able to keep their airways patent without assistance. Experimentally, Washburn (1947) and Horowitz and Shapiro (1951) demonstrated in guinea pigs a significant reduction in the size of the coronoid process, after removing the temporalis muscle. Reduction or absence of the coronoid process and some change in the morphology of the remaining coronoid area was noted. Boyd et al. (1967), also using guinea pigs, demonstrated that removal of the temporalis origin only, while maintaining muscle attachment to the coronoid process, resulted in a reduction in size of the coronoid in only 2 of the 9 animals. They concluded that vascular compromise was a more important factor in skeletal remodeling than was the influence of muscle function. Yellich et al. (1981), experimented on rhesus

FOR AUTHOR USE ONLY

monkeys, measuring the effects of lengthening, detachment, and reattachment of the masseter muscle. Changes in muscle position and length can affect the dento-facial growth configuration of infant primates. The physiological length of the masseter muscle when shortened by surgically shifting the insertion closer to its origin and by moving the coronoid process farther away from its origin, placing the insertions of the masseter and the temporalis in a more posterior position realigned the contractile units of the muscles, causing them to contract in a more anterosuperior direction during chewing. This cascade superior and anterior rotation of the mandible and the maxilla. Yellich et al. (1981) demonstrated muscle adaptation following the elongation of the masseter by inserting a bite-opening appliance; a 50 % return toward the pretreatment length occurred over a 48-week period. Return to the original length of a muscle appears to be a long process (at least a year). In this study, the masseter muscles showed a bilateral lack of electrical activity, but activity returned during the three to six-week postoperative period. The temporalis muscle, however, maintained electrical activity during the entire postoperative period. The lack muscle marker precluded measurement of thechanges in the length of the muscle, although the results of Yellich's experiments (1981) suggested that some muscle adaptation could be predicted. The dry-skull preparations demonstrated dramatically the skeletal changes that occurred. The muscle transposition definitely contributed to the gross skeletal changes, which supports the theory of functional matrices affecting bon growth and remodeling.

FOR AUTHOR USE ONLY

Although mastication is a hallmark attribute of mammals, there is great diversity of all its components.RMasticatory muscle activation and coordination determine the direction of jaw movement, control occlusal force, and deform the skull in a variety of ways. The critical features to understand, then, are action line, force production, and relationship to the cranium. Action line and force production are not as straightforward in the complicated masticatory muscles as in limb muscles, which tend to be arranged more linearly. Similar difficulties with the irregularly shaped skull make the effect of muscles on the bones challenging to model.

One feature in common among mammals is the size and complexity of the muscles of mastication, which occupy much of the head. In terms of size, it is customary to examine the relative mass of individual jaw muscles as a percentage of the whole.1 This procedure illuminates the contrast between species whose masticatory apparatus is dominated by the temporalis muscle (typically generalised species and specialized carnivores with a hinge-like TMJ like cats) and those that emphasise the masseter and medial pterygoid (typically omnivores like primates or herbivores like rabbits, with anteroposterior mobility of the TMJ). However, standardizing each muscle mass to the total masticatory mass obscures whether there are differences in the relative size of the total masticatory mass relative to head size, which remains an unanswered question. Although the same basic terminology (e.g., ‘‘masseter’’ and ‘‘lateral pterygoid’’) is used for all mammals, it is important to realise that these names are based on bony attachment areasand not on function. The anteriorly directed, fascially subdivided superficial masseter muscle of rodents has little functional resemblance to its relatively

FOR AUTHOR USE ONLY

vertical and unitary human counterpart. The jaw muscles have broadly distributed origins and insertions on the skull and mandible, but the main factor that contributes to functional complexity is the fact that most muscle fibers attach to internal aponeuroses rather than to the bones directly. Necessarily, fibers that attach to different surfaces of an aponeurosis must have different orientations, raising the possibility that differential contraction of fibers could change the direction ofmuscle pull, a possibility that has been confirmed in a variety of masticatory muscles.2–5 Thus, action line is not a constant, but varies dynamically throughout a masticatory cycle. Distortion of aponeuroses fromstretching or folding could alter fiber direction evenmore, but results from one muscle, the pig masseter, indicate that aponeurotic stretching is limited to no more than about 5% linear strain.

Muscle anatomy both causes and reflects jaw movement. Muscles (or parts of muscles) may be mostly rotatory (open/ close) or mostly translatory (anterior/posterior or medial/ lateral). The relative importance of upward, medial, and anterior components in the power stroke is associated with startlingly differentmuscleanatomy.Thus,wecan explainwhy the lateral pterygoid is small and unimportant in carnivorans such as cats and ferrets but huge in humans, and why the masseter of rodents is specialised and subdivided. There are some surprises. Parts of the medial pterygoid and/or masseter in several species open the jaw rather than closing it raising some interesting questions about neural circuitry.

FOR AUTHOR USE ONLY

Masticatory muscles, through their direct action on bony attachments and their indirect action in loading the teeth and the jaw joints, constitute the major biomechanical challenge to the skull. Direct effects of a muscle attachment are sensitive to the particular muscles used and to the pattern of muscle coordination. For example, the temporalis and masseter twist the pig braincase in opposite directions, and because these muscles usually act in opposite-side ‘‘couples’’, the effect is exaggerated rather than cancelled. Indirect effects depend on global features such as total muscle force and the particular teeth in occlusion. With regard to total muscle force, the point is simply that the muscles collide the mandible with the upper jaw and thus engender reaction forces at points of contact, specifically the teeth and the TMJs. The former is occlusal force, and its major influence on the skull is to shear the maxilla upward and the mandible downward.13 The reaction force on the TMJs arises from lever mechanics and the fact that the resultant muscle force rarely if ever passes through the bite point. Depending on the particular species, however, it is clear that there are major differences in the geometry of the muscle resultant and hence the relative magnitude of the TMJ reaction load.

The choreographed interplay within and between the complicated masticatory muscles focuses attention on whether, and how, mastication would be changed if one muscle or even just one muscle compartment were incapacitated. This question might seem arcane, because most neuromuscular diseases attack indiscriminately and would not target single muscles. However, it is increasingly common these days for patients to have single muscles paralysed, not only for

FOR AUTHOR USE ONLY

therapeutic, but also for cosmetic reasons.To some extent, the answer depends on which muscle and species. The loss of one masseter may be less of a problem for those taxa in which the inclined planes of the teeth guide the power stroke (such as rabbits) than for those that depend on muscle choreography (such as pigs). In order to maintain occlusal force, however, all species should increase the recruitment level of synergists. Muscle weights suggest that the unparalysed masseter in rabbits hypertrophies. The short-term pig experiment showed that the masseter's synergists for transverse movements, the ipsilateral pterygoids and the contralateral temporalis, were overactive, a prelude to hypertrophy. It is also likely that such changes in muscle usage would alter skull loading. Both the masseter and medial pterygoid create similar strain magnitudes on the pig mandibular condyle, but the orientation of strain is unique for each muscle. Therefore, if one masseter were incapacitated, total joint load would not only be reduced, but also re-oriented. If such conditions were long maintained, as for example with botulinum toxin, bony adaptations would be likely. The growing rabbits in the study by Matic developed smaller condyles on the paralysed side, presumably because of decreased loading. Our own preliminary data on adult rabbits suggest that bone strain in the condyle is indeed reduced by paralysis of the ipsilateral masseter, and that this unloading leads to massive bone loss in the condyle.

FOR AUTHOR USE ONLY

Muscle action and skull biomechanics are inextricably intertwined. In the evolutionary sense, the muscles of mastication are co-adapted with dental morphology and jaw movements to produce species-specific chewing patterns. In

the physiological sense, masticatory muscles comprise the major loading on the skull, influencing its growth and controlling its strength.

Regarding the asymmetric adult patients, the right and left ramus and body length and mandibular angle were strikingly different, whereas there was no significant bilateral skeletal asymmetry in the non-asymmetry group. In our patients with asymmetry, mandibular morphology was characterized by the elongation of one half of the mandible (mandibular body and ramus) and an increase in the gonial angle, which is a characteristic of hemimandibular elongation. The longer mandibular side showed larger mandibular volume in proportion to the degree of chin deviation. It has been proposed that these types of asymmetries are related to asymmetric condylar hyperactivity, that influence not only the growth of the condyle itself, but also the ramus and body of the mandible. However, the mechanism of influence of the condyle cartilage on the length or mass of the mandible has not yet been proven.

The results showed that the medial pterygoid muscle had a significant right-left difference and intergroup difference. However, the masseter, lateral pterygoid,and temporalis did not show a right-left difference. It is interesting that the medial pterygoid volume in the mandibular elongation side decreased in the asymmetry group. As mandibular structures can be influenced by local environmental factors in the form of tension and pressure forces on the muscles adjacent to the bony structure, we tried to determine whether muscular factors can explain mandibular asymmetry.

FOR AUTHOR USE ONLY

The study of adult symmetric subjects showed that people with a large masseter and a medial pterygoid muscle showed that they had a short anterior face and a small gonial angle. In addition to this, there was a correlation between mandibularbody length or ramal height and masticatory muscle size. An increase in the function of the masticatory muscle is associated with anterior growth rotation of the mandible and well-developed angular, coronoid, and condyle process. It had been reported that there is a correlation between a larger adult masseter and medial pterygoid volume and a small mandibular angle and a longer ramal height. There was also a correlation between the larger medial pterygoid volume and a longer body length. If this relation does exist in patients with facial asymmetry, it may be expected that their ramal or body length is relatively longer and that their gonial angle is smaller in the side that has larger masseter or medial pterygoid volume. However, in patients with asymmetry, larger masticatory muscle volume did not accompany longer skeletal measurements. In particular, the medial pterygoid volume decreased in proportion to the increase in the body or ramal length. These findings are contrary to previous reports on symmetrical adultsubject.

Muscles And Mandible

The mandibular muscles ie masseter, temporalis, medial pterygoid, and lateral pterygoid have been discussed earlier. Mandibular muscle function and formcorrelate with the morphologic features of the craniomandibular apparatus to which the muscles are related. Many attempts have been made to investigate the

seemingly complex relationship between features of the mandibular muscles and the various facial patterns. [63]

Mandibles can grow in more vertical or horizontal directions. Several authors have attempted to describe the normal variation in the vertical and horizontal dimension of the human face. [63]

Relationship Between Craniofacial Morphology And TheMandibular Muscles

Bite-force and facial morphology

Bite force is a direct measure of muscle activity. Significantly smaller maximum molar bite forces have been found in dolichofacial subjects during maximum effort than in mesofacial and brachyfacial subjects. This implies a correlation between bite force and facial morphology, and these findings have been used to support the theory that the form of the face partly depends on the strength of the mandibular muscles. Ingervall and Helkimo(1978) found that adults with weak muscles have a greater variation in facial morphology than those with strong muscles, and it was believed that this argues for the primary importance of the mandibular muscles in forming the face. [64] Kiliaridis(1995) suggested that strong muscles produce faces with similar morphologic features, whereas weak muscles cannot influence the morphology to such an extent. Variation between people with weak muscles is therefore wide, and those with weak mandibular muscles can belong to either the mesofacial or the dolichofacial group. [63]

FOR AUTHOR USE ONLY

Cross-sectional area of the mandibular muscles and facial morphology Various authors have described the relationship between the cross-sectional area of the mandibular muscles and facial morphology. [65,66] It has been observed that the masseter and medial pterygoid muscles have large cross-sections in subjects with short anterior face heights and small gonial angles. On the contrary, Van Spronsen et al (1991) reported no significant correlations between either anterior facial height or posterior facial height and any jaw elevator cross sectional areas with normal skull shapes, when studied with magnetic resonance imaging. [67]

An important determinant of the maximum force that can be produced by a muscle is apparently its cross-sectional area. Significant positive correlations have been reported between the cross-sectional areas of the masseter and medial pterygoid and the maximum molar bite force. Hannam and Wood found a statistically significant correlation between masseter and medial pterygoid cross- sectional areas and molar bite force but no correlation between cross-sectional areas and the muscle moment arms.

FOR AUTHOR USE ONLY

Position, orientation and mechanical advantage of the mandibular muscles According to Takada et al (1984) short posterior face height with steep mandibular plane and large gonial angles is often associated with an anteriorly inclined superficial masseter relative to the occlusal plane and a superior positioning of its insertion on the mandible. This is consistent with the observations of Proctor and DeVincenzo (1970) that the superficial masseter was

angled considerably more anteriorly with a much more acute angle to the occlusal plane in a dolichofacial specimen when compared with a brachyfacial specimen.

[68] Van Spronsen et al,(1996) observed that the orientation of the mandibular muscles in mesofacial and dolichofacial subjects can be strikingly similar. [69] The issue of whether masseter angulation is constant relative to the occlusal plane is controversial. Proctor and DeVincenzo noted a constant angular relationship (about 69°) between the superficial masseters and the occlusal planes in two groups with contrasting vertical facial patterns, others have not been able to demonstrate such a constant relationship.

The efficiency with which a muscle generates a force at a particular point on the lever arm would seem to be related to its mechanical advantage, which has been defined as the ratio of the moment arm of the muscle to the moment arm of the load. [63] Throckmorton et al explained that the significantly smaller bite force of dolichofacial subjects might to a large extent be due to the reduced mechanical advantage of the mandibular muscles in these subjects. Although this has formed the basis for the contemporarily accepted concept of muscular mechanical advantage, it is not universally accepted. Sasaki et al (1989) for instance, found that the variation of maximum bite force could be accounted for largely by musclecrosssectional areas rather than simply by muscle lever arms. [70]

Cause and effect relationship between muscle function and craniofacial morphology

There is often a relationship between form and function, but it is not known whether a genetically determined facial morphology dictates the strength of the mandibular muscles or whether a strong musculature influences the form of the face. [71] In animal studies, it has been shown that interference with the development of the jaw and facial muscles can lead to major changes in the shapes of jaw bones. It has also been shown that human subjects with strong bite forces tend to have brachyfacial patterns, in contrast to those with weak bite forces, who tend to have dolichofacial patterns. This difference in bite force has led to much speculation about the etiology of vertical facial patterns. According toProffit and Fields (1983) , it is possible that the lower bite force in dolichofacial people might allow greater eruption of the posterior teeth than might otherwise occur, and so are directly related to the excessive tooth eruption and backward rotation of the mandible often seen in such subjects. [72] Ingervall and Helkimo suggested that the interindividual form of the face is smaller in persons withstrong muscles than in those with weak muscles. This would support the hypothesis that the muscles do actually contribute to the final shape of the face. Further support for this theory presumably came from the findings of Ingervalland Bitsanis(1987), who showed that training the jaw muscles in dolichofacial children strengthened these muscles and induced a favorable anterior mandibular growth rotation. [73]

Whether the bite force differences play a role in determining the ultimate facial morphology or merely reflect the mechanical advantage obtained by the muscles in the different facial types has been a matter of some controversy. The model

FOR AUTHOR USE ONLY

proposed by Throckmorton et al, which depicts the unfavorable mechanical position of the mandibular muscles in dolichofacial subjects, implies that the muscular function is influenced by skeletal form. The fact that the dolichofacial pattern can be recognized before an age at which decreased occlusal forces are present strongly suggests that the decreased forces are an effect of the condition, rather than a cause.

It has been suggested that subjects with increased vertical craniofacial dimensions have relatively obliquely oriented jaw muscles, with a consequent reduced potential to restrain the vertical component of craniofacial growth. [74] This situation is obviously different to that in brachyfacial subjects, with vertically oriented jaw muscles, which would be expected to restrain the vertical componentof growth and contribute to the forward rotation of the mandible; this is a characteristic of this group. The relationship between the growth patterns of the skull and characteristic jaw muscle function and orientation in subjects with increased vertical dimension has received considerable attention. [67,71] None of these studies, however, has provided an ultimate answer about whether jaw muscle function determines the outcome of craniofacial growth or vice versa.

Masticatory Muscles And Maxilla

Various studies have shown an association between the functional capacity of the masticatory muscles and craniofacial morphology. A positive association betweencross-sectional areas or

thickness of masticatory muscles and craniofacial widths has been reported, i.e. subjects with thicker masticatory muscles have broader faces. The muscles found to be involved in this relationship were the temporal muscle, the masseter and the medial pterygoid muscles. [67,66] Since there is an association between masticatory muscle size and craniofacial width, a similar association might be expected toexist regarding dental arch width. The findings of the present study suggest that there is a significant association between masseter muscle thickness and maxillary arch width in female subjects. The multiple regression model that used masseter muscle thickness and age as independent variables could explain approximately one-quarter of the total variance in intermolar width. In male subjects, no significant association between maxillary arch width and masseter thickness was recorded. This finding could be related to the lack of relationship between masseter muscle thickness and measurements describing the width of the face in adult males. [65]

In patients suffering from myotonic dystrophy, a decreased width of the palatehas been reported. This might be due to muscle weakness but also to other factors (e.g. head posture) that affect equilibrium both sexes between 3 and 13 years of age, after which it remains stable in males, whereas it decreases slightly in females. Males have been found to have a significantly larger maxillary intermolar width than females in all age groups. The greater arch width found in medieval dentitions compared with those from a modern control sample is considered to be due mainly to differences in diet and masticatory function. Masumoto et al. (2001) reported that the lower molars of skulls with a long facial

FOR AUTHOR USE ONLY

configuration were more lingually inclined than in skulls with an average or short facial configuration, this difference possibly being related to variations in the functional capacity of the masticatory muscles. This might reflect a compensatory mechanism of the dental arches to offset a smaller maxillary base. The masseter muscle has been found to be thinner on the crossbite side than on the normal side in patients with functional lateral crossbite. The functional capacity of the masticatory muscles should be considered as one of the factors influencing the width of the maxillary dental arch. [75] Increase in the muscle thickness leds to an increase in the dental arch width. This is in agreement with the studies by Kiliaridis et all and Katsaros where they affirm that the functional capacity of the masticatory muscles may be considered as one of the factors influencing the width of the maxillary dental Imasseter muscle increased the sagittal growth, while limiting the vertical growth of jaws. [75] It tended to make the face grow in a more horizontal pattern. Increased masseter thickness increased the length of the maxillary arch. Subjects with thicker masseter muscles had a wider maxillary dental arch. . In previous studieisit has been hypothesized that the increased loading of the jaws due to masticatory muscle hyperfunction may lead to increased sutural growth and bone apposition, resulting in an increased transverse growth of the maxilla and broader bone bases for the dental arches. Maxillary width is smaller in masticatory hypofunction individuals.

FOR AUTHOR USE ONLY

Currently, it is widely accepted that masticatory muscle function is closely correlated with craniofacial morphology. During mastication and clenching, the masticatory muscles contract strongly but momentarily. On the other hand, the masticatory muscles work continuously to stabilize the position of the mandible, although the activity may be weak. Such muscle activity is induced widely during daytime in usual daily life. Thus, it would appear a reasonable, assumption that such low but widely induced masticatory muscle activity during daytime might play an important role in craniofacial morphogenesis. Given these considerations, Miyamoto et al(1996) recording the masseter muscle activity for a consecutive 24 hour period, demonstrated a number of low-amplitude bursts widely distributed during the whole day.[76] Furthermore, Ueda et al(1998) indicated a close interaction between masticatory muscle activity for 3 hours during daytime and vertical craniofacial morphology in adults. [77]

Previous studies, focusing on bite force, mandibular movement, and muscle activity revealed the differences in masticatory function between children and adults. Horikawa et al (1985) and Yashiki et al (1994) found that the temporal muscle works mainly in children, whereas the masseter muscle exhibits prominent activities in adults during maximum clenching and chewing. [78,79] Therefore, it is assumed that there might be two differences in the nature of masticatory muscle activity between children and adults; one is total duration of masticatory muscle activity during daytime, and the other is a significant relationship between the duration of muscle activity and craniofacial morphology. Thus, it is important to

FOR AUTHOR USE ONLY

examine the relationship between masticatory muscle activity and craniofacial morphology and to reveal the difference between children and adults. children have longer temporal muscle activity and adults have longer masseter muscle activity during daytime, although the muscle activities essentially consisted of widely induced low-amplitude bursts in both groups. The duration of masseter and digastric muscle activities was related significantly with the vertical facial type in both children and adults, whereas the duration of temporal muscle activity presented no significant relationships .The total duration of masseter muscle activity on levels one and two was significantly longer in adults than in children. On the contrary, the total duration of temporal muscle activity on all levels was prominently longer in children than in adults. A possible explanation for such differences may be the fact that development of the dentition, temporomandibular joint and masticatory muscles has not been completed in children. The glenoid fossa is almost flat in the neonate. Therefore, the mandible can move freely in the horizontal direction, subsequently forcing the temporal muscle to work to stabilize the mandibular posture in children. It is also assumed from the present findings that children and adults may have different behaviors of the masseter and temporal muscles during the daytime. An interesting finding in this study was thatthe total duration of digastrics muscle activity was similar in children and adults. This may be accounted for by the role of digastric muscle. Activity of the digastric muscle is known to accompany the lateral pterygoid muscle activity during mouth opening. Because orofacial functions such as breathing, speaking, and swallowing do not require substantial jaw opening during the daytime, it may

FOR AUTHOR USE ONLY

be reasonably assumed that the differences in these muscle activities are not significant between children and adults. Masseter muscle activity, in this study, was significantly longer in the low angle group than in the high angle group for both children and adults. Various studies demonstrated a negative correlation between the mandibular plane or gonial angles, and masseter muscle activity atthe maximum voluntary clenching.

In addition, the cross-sectional area of the masseter muscle, measured with ultrasonography, exhibited a negative correlation with the vertical facial height. Thus, it may be confirmed that comparatively low muscle activity during normal daily life as well as greater muscle activity or the corresponding muscle size is significantly related to vertical morphology of the craniofacial skeleton. On the other hand, no significant interrelations are found between temporal muscle activity and the vertical craniofacial morphology, as was also demonstrated in a previous study. [80]

In contrast, a negative correlation is revealed between the mandibular plane angle and temporal muscle activity during maximum clenching and chewing in other studies. [81,82] The temporal muscle has less prominent interrelation with the morphology of the mandible, playing a different role in the stomatognathic function from the masseter and digastric muscle. [83] Longer duration of digastric muscle activity is present in the low angle group compared with the high angle group, as is the case with the masseter muscle. [84]The duration of digastric muscle activity as well as opening force and muscle thickness might thus have a close relationship with craniofacial morphology.

FOR AUTHOR USE ONLY

Masseter and digastric muscle activity during the daytime has similar interrelation with vertical facial type which can be explained by a positive correlation between the masseter and digastric muscle activities. Because greaterjaw opening force is required to extend the thicker jaw closing muscles, even if they are not under activation, it is speculated that high correlation may be found between the masseter and digastric muscle activities. [84] No significant differences in the duration of the masseter, temporal, and digastric muscle activities are found between both sexes. Miyamoto et al(1996) found no significant sexual differences in 24-hour masseter muscle activity. [76] This may be explained by the reference potential level, which was defined in this and previous studies to standardize the muscle activity for each subject and to eliminate the individual variations with a special reference to the maximum voluntary clenching. On the other hand, the maximum discharge voltage of the digastric muscle, used as the reference, was determined during maximum voluntary opening, while maximum voluntary clenching was used for the masseter and temporal muscles. Although both maximum voluntary opening and clenching may produce the greatest activity ofjaw opening and closing muscles, it remains unclear whether the present resultsmay be influenced by the difference in these performances to define the maximum discharge voltage Significant differences in the duration of masseter and temporal muscle activities were found between children and adults. Children and adults had longer total duration of the temporal and masseter muscle activity, respectively, during daytime, although the digastric muscle experienced almost the same duration in children and adults. Meanwhile, a significant correlation between the duration of masseter and digastric muscle activities and craniofacial morphology was revealed in both children and adults, whereas the temporal muscle presented no significant association with craniofacial morphology.

FOR AUTHOR USE ONLY

Currently, the mechanisms by which nonsyndromic deviations in craniofacial morphology develop are not fully understood, but recent work has shown that altered masticatory functioning has significant effects on the face and neurocranium . [84] For example, mice with a hypermuscular phenotype due to loss of myostatin, a growth factor which negatively regulates muscle fiber size, have more brachycephalic and smaller cranial vaults, decreased maxillary length, and a distinctive mandibular shape, which replicates the "rocker mandible" described previously in some humans. The rocker morphology appears during the adolescent growth period when increasing muscle forces influence mandibular shape and a similar morphology seen in Inuit mandibles is attributed to the vigorous chewing characteristic of Eskimo populations. Masticatory muscle function is a key environmental influence on these bony craniofacial areas through force application during growth. Human craniofacial skeletal dimensions correlate with masticatory muscle volume because this is directly related to the loads generated during normal functioning. The intensity of masticatory activity in young adults in modern human populations (eating a highly processed diet) is extremely limited, with teeth estimated to be in occlusion for only about 6 to 7 minutes in a 24-hour cycle.20 Therefore, masticatory activity per se contributes relatively little to normal function of masticatory muscles in the population.

FOR AUTHOR USE ONLY

By contrast, muscle tone for postural purposes appears to be more important as, even though the force is small and difficult to quantitate it undoubtedly maintains the freeway space between the teeth and helps to protect the airway—activities that have a much higher duty cycle. Perhaps the best demonstration of how variation in muscle activity affects craniofacial growth is the example of children with Duchenne muscular dystrophy who develop severe open bite malocclusions due to decreasing muscle forces transmitted to the face as the condition progresses.

Specific aspects of orthodontic treatment with reference to themandibular muscles and vertical facial pattern

Extrusive mechanics

Most orthodontic mechanics are extrusive, and this extrusion appears to maintain or even increase the vertical dimension during orthodontic treatment. It is not surprising, therefore, that there is a greater potential for the undesirable extrusion of molars in dolichofacial subjects compared with brachyfacials, who have stronger musculature that tends to resist extrusive forces during orthodontic treatment. [63] If molar extrusion does occur during treatment in brachyfacial patients, there is likely to be a strong tendency toward reintrusion through the influence of the muscles during swallowing and chewing. Thus, it might bedifficult to cause permanent extrusion of the molars and backward rotation of the mandible in such patients, even though this is a main aim of treatment. During treatment, extrusive forces with such mechanics as intermaxillary elastics or

FOR AUTHOR USE ONLY

particular headgears should probably be avoided in patients with backward- rotating tendencies to try to limit, as much as possible, any undesirable backward rotation of the mandible. Vaden and Kiser(1996) advocated that, in such patients, it is crucial to really control the vertical dimension if stability, facial balance, and harmony are the ultimate goals of treatment. [85]

Extractions and timing of treatment

Staggers reported on the changes in the vertical dimension between premolar and second molar extraction groups and found no significant differences between them. It has been shown that, if premolars are extracted in dolichofacial patients, there is still likely to be a slight increase in the vertical dimension, whereas, in brachyfacial patients, there is likely to be no change or even a slight decrease. Extrusion of posterior teeth with growth and treatment has been shown to be the reason for this usual maintenance of the vertical dimension during treatmentinvolving premolar extractions. [63]

FOR AUTHOR USE ONLY

The recognition of different muscular patterns, growth rotations of the mandible, and profile concavity or convexity will influence the premolar extraction decision in each patient. Pubertal growth and the E-spaces are important components of the orthodontic management of most brachyfacial patients, whose treatment often begins in the late mixed dentition without premolar extractions. In dolichofacial patients, treatment often begins later (unless severe crowding warrants early extraction with space maintenance). The aim of not only aligning teeth but also placing them in positions of muscular stability and facial balance will often require the extraction of premolars in dolichofacial patients. Although Gianelly

(1994) did not mention vertical facial pattern or the influence of the muscles on orthodontic treatment, he did discuss the notion of preserving the E-spaces by starting treatment in the late mixed dentition stage. [86] According to him, the leeway space would allow the relief of crowding in up to 75% of patients, enabling much orthodontic treatment to be carried out without premolar extractions. This might seem to be an ideal approach to the treatment of brachyfacial patients. Vaden (1998) however, claimed that, in most dolichofacial patients, the extraction of premolars is absolutely necessary. [87] The greater tendency toward premolar extractions in dolichofacial patients than in brachyfacials has been discussed previously [63]

.

Surgical considerations

Jacobs and Sinclair (1983) suggested that the optimum in efficiency of treatment, stability, and esthetic change in orthognathic surgery patients would be obtained by postponing the levelling of mandibular curves of Spee until after surgery. [88] In Class II deep-bite patients, it is common practice to leave final levelling until after surgery so that, at least in theory, postsurgical extrusion of the posterior teeth will enhance any surgical increase in lower face height. Surgical manipulation of the jaws alters the environment in all three dimensions so the teeth can be placed in their final, well-detailed positions. If, presurgical levelling is attempted in brachyfacial patients, it would have to overcome the heavy bite forces associated with such patterns. In other patients with longer lower anterior facial heights, most of the levelling should probably be carried out before surgery to avoid, as

FOR AUTHOR USE ONLY

much as possible, postsurgical extrusive effects. Arch coordination and preparation are generally more easily achieved in these longer-faced patients because of the decreased vertical muscular anchorage.

Muscular anchorage

Bench et al (1978) introduced the concept of muscular anchorage. [89] According to this concept, the facial type described by the cephalometric morphology reflects a particular underlying muscular pattern. The teeth would be controlled with natural anchorage in a brachyfacial pattern, where the musculature is strong, but there would be less muscular anchorage in dolichofacial subjects with weak mandibular musculature. Weaker musculature would be less able to overcome the molar- extruding and bite-opening effects of orthodontic treatment. Ricketts et al claimed that the values for the oral gnomon and facial gnomon were excellent indicators of mandibular morphology and the associated muscular function.

FOR AUTHOR USE ONLY

Retention

The position and function of the lips are well accepted to influence incisor alignment and stability. The facial and mandibular muscles are also critical influences. Ricketts et al. suggested that preferred incisal positions and angulations at the end of active treatment might vary depending on the underlying vertical facial type, with brachyfacial patients tolerating more protrusive and proclined incisors than dolichofacial patients. It has been suggested that brachyfacial patterns might allow greater expansion of the arches during

treatment, in contrast to dolichofacial patterns with generally weaker mandibular muscle forces that might allow less expansion during treatment. Although the pretreatment vertical facial pattern has been discussed as a possible factor in determining occlusal stability after treatment, no direct relationship has beenfound. [63]

FOR AUTHOR USE ONLY

Introduction

Masticatory muscle function and its influence on craniofacial growth have been investigated in animal experiments and clinical studies. These investigations commonly show that the elevator muscles of the mandible influence transverse and vertical facial dimensions. Increased loading of the jaws associated withmasticatory muscle function increases sutural growth and stimulates bone apposition, resulting in greater transverse growth of the maxilla and broader bone bases for the dental arches.

Animal Studies

Numerous experimental studies have examined the mechanism behind the interplay of masticatory muscle function and craniofacial growth. Various experimental methods have been used to modify masticatory muscle function, including denervation or resection of masticatory muscles, extraction or grinding of functioning teeth, insertion of devices in the mouth to alter mastication, and alteration of the consistency of the diet. [90] The advantage of the latter model is thatthe effects of an altered function can be observed in an intact masticatory system, significantly simplifying the interpretation of experimental results. Altering the consistency of the diet in laboratory animals induces changes in the demands of biting force level, masticatory activity and behavior, and these in turn alter the composition and diameter of the fiber types in the animal's masticatory muscles. These changes probably influence the tension that the masticatory muscles apply to the craniofacial skeleton, thereby altering its growth. However, experimental

FOR AUTHOR USE ONLY

results with different animal species are not always consistent. The prevalence of malocclusions has increased among contemporary populations who have changed from a primitive to an industrialized and refined diet. Studies in macaques and squirrel monkeys fed soft diets have shown reduced maxillary and mandibular widths, palate heights, and poorer craniofacial growth. However, the maxillary and mandibular arch lengths were not significantly affected by dietary consistency in squirrel monkeys. Furthermore, baboons fed a soft diet showed relatively increased variability, reduced correlations in their oral-facial structures, and disruption of normal occlusion. [91] However, because of problems in experimental design, including lack of control of age, gender, genetic background, and nutrition of these animals, the results of these studies may not be suitable to explain the previously observed changes in man. Ciochon and coworkers (1997) followed the growth of 8 young female Yucatan minipigs fed hard or soft diets for 8 months. [92] The hard-diet minipigs had steeper frontal profiles, while the soft-diet ones presented more horizontal crania. The hard-diet group showed greater bizygomatic widths, shorter palates, and smaller minimum distance between temporal crests than the soft-diet animals. In the mandible, animals fed a hard diet showed wider posterior dimensions, as well as thicker, higher, and more vertically directed rami than the soft-diet group. Ogaard and Larsson (2003), studied 17 young domestic pigs of both sexes fed hard or soft diets for 22 months. [93] They found no significant differences in the morphology and dimension of the craniofacial regions between the groups. The small sample sizes of these two investigations, along with mixed sexes in the sample and the lack of the strict

FOR AUTHOR USE ONLY

control of food consistency in the Swedish study, may have contributed to these conflicting conclusions. The experimental model of altering the consistency of the diet has been mainly used in small animals such as the rat. Although great variation exists in these studies concerning the strains, sex, and ages of the rats involved in these experiments, the duration of the experimental periods (range from 4 to 18 weeks), and in the consistency of the diet, they do share common findings that elucidate the role of masticatory function in the craniofacial growth of this animal model. The decreased functional demand of a soft diet causes structural changes in the masticatory muscles and alteration of their contractive capacity, as indicated by changes in the muscle fiber types and the smaller size of the fibers. These changes could explain the low biting forces measured in the soft-diet animals. Rats fed a soft diet generally have maxillae with smaller transverse dimension. [94,95] Low biting and chewing forces may induce changes in bone remodeling and in sutural growth of the craniofacial region. Behrents and coworkers (1978) for example, have proposed that bite forces could providetensile strain sufficient to cause a separation of the sagittal suture of the skull. [96] The fact that bone remodeling in sutures responds to functional alterations could explain why rats with less tension in the lateral part of their nasal bones (due to a reduced masticatory and biting function) showed reduced width of sutures in the anterior part of their snout and appearance of several synostoses in their internasal suture. A morphometric study verified a narrower sutural space, an almost parallel orientation of bony surfaces of the facial sutures, and reduced sutural bone apposition in rats after a reduced functional demand. This supports histological,

FOR AUTHOR USE ONLY

histochemical, and biochemical studies showing that alterations in dietary consistency can result in changes of varying magnitude in the morphology and the metabolism of the intermaxillary suture cartilage. Reduced function also caused changes in the size and dimensions of the alveolar process, that is, the width, height, and thickness of alveolar bone. Changes in bone apposition were observed not only in the vicinity of the insertion of the elevator muscles, but also in areas where increased apposition reinforces the bone so that it is able to withstand the higher bending forces in animals fed a hard diet. [97] These alterations in bone modeling and sutural growth may underlie the greater upward rotation of the upper viscerocranium, the reduced growth of the angle of the mandible seen radiographically and the reduced transversal palatal width observed in dry skulls of animals fed a soft diet. [95] Reducing mastication in hypocalcemic rats, byfeeding the animals a soft diet, was a powerful determinant of remodeling behavior at certain sites, even with this metabolic bone disturbance. Rats fed asoft diet also have smaller and more posteriorly rotated mandibles. The cross-sectional area and width of the molar and incisor alveolar processes, and themolar periodontal spaces, are greater in rats fed hard diet, possibly an adaptation to support the increased incising and occlusal loading needed to process the hard diet. The response of the different functional units of the mandible to changes in functional strain was evaluated by using a computer-aided image-analysis system that measured the bone mass on roentgenograms (in relation to an aluminum step wedge, ie, “aluminum equivalent ” mass). Reduced muscle function decreased bone mineral mass in the alveolar bone of the molars and the incisors, at the

FOR AUTHOR USE ONLY

angular process (the area of the insertion of the masseter and pterygoideus medialis), and at the bony bulk ascending to the condylar process, possibly in accordance with the strain distribution of the masticatory forces. Lower levels of bone mass in areas with a high bone apposition rate apparently result from decreased bone apposition, whereas in areas with a low bone apposition rate bone mass loss seemed to be an effect of decreased bone density. Because the condyle is considered to be a mandibular growth zone directly affected by functional alterations, several investigations have examined how changing the consistency of the diet affects the temporomandibular joint (TMJ) in growing animals. Significantly smaller condyles were found in the soft-diet.[98] Condylar cartilage was significantly thicker at the posterior part and thinner at the anterior part in soft-diet groups, indicating that low masticatory function, presumably with altered stress distribution in the TMJ area, decreased condylar growth and decreased the thickness of the cartilage. Although studies using rodents provide insights into the basic mechanisms of how masticatory function may influence craniofacial growth, direct extrapolations to humans are not appropriate because the masticatory system of rodents is quite different in terms of both anatomy and function. It is possible that the same alteration of masticatory function might have a different impact on craniofacial growth in species with different masticatory systems. For example, ferrets are carnivores and have a masticatory system that differs substantially from that of rats.[90] A rodent bites off solid food with its sharp upper and lower incisors, and grinds the pieces with its molars using mainly bilateral backward and forward mandibular movements. In contrast, the posterior

FOR AUTHOR USE ONLY

teeth of ferrets perform a function mechanically equivalent to that of a pair of scissors; the far distal molars are only occasionally used to crush food items. The ferret is unable to grind food with its molars due to the anatomy of its TMJ. Therefore, ferrets have to struggle to crush hard pellets, applying great effort for a longer period than ferrets fed a soft diet, which is hardly crunched before swallowing. After 6 months of vigorous mastication the elevator muscles of the animals fed a hard diet showed a training effect in the form of thicker muscle fibers, not only in the temporalis and masseter muscles, but also in the digastric muscle.[99] These results confirm the findings for the masseter muscle in the rat, but differ from the findings for the digastric muscle where no differences were found in the size of the muscle fibers between the soft- and the hard diet groups in the rat. Presumably ferrets use the jaw depressors differently during mastication than rats, leading to different digastric muscle reactions to the alteration in diet. The ferrets fed a soft diet had the hard palate plane located further from the cranial base plane, they showed smaller interfrontal and interparietal widths, and they had more slender zygomatic arches than ferrets fed a hard diet. Furthermore, the coronoid process was generally shorter and narrower in the group fed a soft diet.[75] However, it should be emphasized that altered masticatory muscle function had less impact on craniofacial morphology of the growing ferrets than has been reported in growing rats. These differences are presumably related to different modes of mastication, craniofacial anatomy, and growth patterns of the two species. Sutural growth plays an important determining role in how craniofacial dimensions change in response to alterations of masticatory function.

FOR AUTHOR USE ONLY

As a general rule, sutural growth is promoted by tension and retarded by compression. Sutural strains may vary between, and even within, given sutures during functional loading, depending on the suture's direction relative to loading forces, the attachment and orientation of the muscles, the location of the masticatory muscles in relation to the rest of the skull and the teeth, and last, but not least, the time and order of suture fusion. All these factors vary significantly among different species. In ferrets all the masticatory muscles are situated posterior to the orbital crest, while in rats the anterior deep masseter reaches as faras the medial wall of the infraorbital foramen.

The influence of the masticatory hypofunction on the craniofacial growth and development in rats

There are various opinions about the influence of the function on the maxillomandibular bone structure in the literature. Some authors reported that form and volumes of maxillomandibular bones were determined by genetic factors. Others reported that not only genetic factors but also functional stimuli are important and with the lack of these stimuli, the maxilla and mandible may not reach their full dimensions. Studies in human beings have shown a clear correlation between muscle function and facial structure. In recent studies, the size of the masticatory muscles was correlated with the facial structure and the masticatory muscle orientation was also related to the skeletal structure. The findings of human studies are in agreement with the results of the experimental animal studies on low muscle function, induced by feeding a soft diet. Decreased

FOR AUTHOR USE ONLY

size of the mandible and a decreased transversal width of the maxilla were determined in these rat experiments. In other studies, it was shown that hardand soft diets influenced the craniofacial and mandibular growth and structure in the growing rats.[65]

There are three rat experiments studying the effects of masticatory hypofunction in the literature. Watt and Williams weighed cranial and mandibular bone weights in the hard and soft diet groups and they measured buccolingual thickness of the mandibular corpus. Watt and Williams found no difference in the cranial bone weight between the groups, but they determined that mandibular bone weight wasreduced and maxillary width, thickness of the mandibular corpus were also reduced in the soft diet group. Beecher and Corruccini studied the effects of normal and soft diet on the growth and development for 4months in 21-day-old rats. At the end of this experiment, they found no significant difference between animal weights but they showed that maxillary width was reduced because of masticatory hypofunction. Kiliaridis et al used 28 dayold rates in their study intwo separate normal and soft diet groups and followed up the experiment for 28 days. Rats were weighed at the beginning and at the end of the experiment and cephalometric analysis was carried out to evaluate craniofacial changes. Kiliaridiset al reported that body weights increased in both normal and soft diet group along the experiment, but that body weight increase in the soft diet group was less than the normal group and the difference between the two groups was statistically significant. Kiliaridis et al stated that the body weight differences could be an important causal factor in the craniofacial changes. At the end of 28 days of

FOR AUTHOR USE ONLY

experiment time, in the soft diet group, total skull length and skull height measured in the occipital region were significantly reduced, upper anterior face height and lower incisor alveolar height were significantly increased compared with those of the control group. It was determined that appositional development of gonial angle in mandible was reduced. In the second article by Engstom et al., the material of the first study was used, sections taken from growth sites were stained by histochemical methods and bone remodeling in rats fed a soft diet has been assessed. This study m has shown that masticatory hypofunction causes a specific alteration in the bone apposition pattern in cortical bone and in sutures and the overall apposition pattern was decreased. In two of these studies summarized previously, few direct skeletal measurements were done. In the other two articles al mentioned previously, radiographic and histologic methods were used, whereas in the current study, the skeletal and dental measurements were made directly on the skulls of the animals.[65]

In study by Ulgen et al the diets of the normal function and hypofunction groups were very carefully planned to prevent the growth and development deficiencydue to malnutrition. For this purpose, rats in each group were weighed on day 30 and day 90 and no significant difference has been found between the mean body weights of the experimental and control group animals. This result showed that there was no growth deficiency because of nutritional deficiency in either the experimental or the control groups. The total skull length, lower anterior face height, and total anterior face height in the hypofunction group were significantly reduced compared with those of the control group. Kiliaridis et al also found a

FOR AUTHOR USE ONLY

reduction in the total skull length in a previous report. As in agreement with the findings of the previous studies, %9 it was found that maxillary width , ramus mandibula height(Cond-GoT), and corpus mandibula height (Me-Ma) in the masticatory hypofunction group were smaller than those of the control group. In addition, it was determined that premaxillary length in the hypofunction groupwas also smaller than the control group. But foramen incisivum width in the hypofunction group was found greater than the control group. In the normal masticatory function group, the foramen incisivum has been narrowed because of the continuous appositions around itself, whereas in the hypofunction group less bone apposition, due to less functional stimuli, resulted in a larger foramen incisivum. Kiliaridis et al. found significant difference on the cranial growth. Kiliaridis et al has already reported that the body weight differences could be an important causal factor in the craniofacial structure changes in the soft diet group.[65]

FOR AUTHOR USE ONLY

Human Studies

The animal experiments illustrate the influence of the masticatory muscles on the basic mechanisms of craniofacial growth (ie, on bone remodeling, and condylar and sutural growth). They also show that similar alterations of masticatory function can induce different craniofacial

growth changes among species with different masticatory systems. Thus, the direct extrapola- tion of animal experiments to humans is not valid. The literature showing associations between masticatory muscle function and craniofacial

morphology is enormous. Anthropologic studies have reported a low frequency of malocclusions in populations with primitive living conditions. [100,101] The frequency of malocclusions appears to have increased after human populations came under the influence of industrialized civilization. This is thought to be either a result of the premature loss of deciduous teeth due to caries or to hypofunction of the masticatory muscles due to alteration in the consistency ofmthe diet that reduced the forces applied to them jaws. [90] Medieval skulls show a lower frequency and lower severity of malocclusions than in contemporary individuals. These medieval skulls characteristically have a small intermaxillary angle, a small gonial angle, and broad jaws. The excessive attrition observed on the teeth of the medieval skulls suggests extensive function of the masticatory muscles, making it tempting to relate the high functional demands of the masticatory muscles of these individuals to the morphological characteristics of their skulls. [90] However, other factors, such as increased mouth breathing due toan increased prevalence of allergies, may have contributed to the morphologic differences. Some contemporary individuals also show advanced stages of dental wear and increased levels of masticatory muscle activity, mainly due to bruxism. These same individuals also have a low incidence of malocclusions and arecharacterized by a short lower faces, smaller intermaxillary angles, and small gonial angles. Similar phenotypes have been reported for wrestlers,who in general, are characterized by a well-developed muscular system and have, furthermore, undergone heavy resistance training. [90] Wrestlers have wide and well-developed dental arches and a low frequency of malocclusions. Their

FOR AUTHOR USE ONLY

craniofacial morphology is characterized by a short lower face, small intermaxillary angle, and a decreased gonial angle, possibly a result of increased bone strain on the dentofacial structures during their growth period. This could have been caused either by the forces exerted directly during the sport or by occlusal forces generated by their well-trained masticatory muscles. The possibility of training masticatory muscles was tested in a group of young adults by introducing them to systematic chewing exercises using a hard chewing gum. After 1 month's training their maximal bite force had increased. Clinically, this had a positive effect in the treatment of anterior open bite. [102] In contrast, craniofacial morphology deteriorates in patients with myotonic dystrophy. These patients have low bite-force levels and reduced masticatory muscleelectromyographic activity, and their growth is characterized by a vertical growth pattern and a high incidence of malocclusions, including distal occlusion, anterior open bite, lateral cross bite, and crowding. Another method of investigating the relation between masticatory muscle function and facial morphology has been to relate the functional capacity of the subjects' masticatory apparatus to their facial morphology. Different methods have been used in adults to evaluate the relation between facial characteristics and their functional capacity, such as the maximal bite force,and morphological measurements of the masticatory muscles recorded by computed tomography, magnetic resonance imaging, or ultrasonography. A general consensus in all these studies is that subjects with strong or thick mandibular elevator muscles have wider transversal head dimensions. Tendencies toward parallelism between jaw bases and between occlusal smaller lower facial

FOR AUTHOR USE ONLY

heights, and more rectangular shape of the face were also observed in some of the studies.

Proffit and Fields (1983) detected no statistical differences between the bite force of long-face and normal children, suggesting that long-face children had similar bite-force levels as normal ones.[103] However, this may have been a typical type II error due to a small sample studied and one large methodological error; it is not easy to motivate young children to bite with maximum force, and some of the "normal" children in the study produced maximal bite forces close to zero! Unless the children suffered from a muscle disease, such low levels of maximal bite force are probably not physiologic. The authors even noted that "some of the children found it difficult to cooperate with the laboratory procedures." In contrast, the bite-force levels of long-face adults were much lower than those of normal-face adults, approximately at the same level as the long-face children.

The long-face group is more homogeneous, with consistently thinner muscles and lower bite forces, while normal-face individuals vary widely in the thickness of their muscles and thus their bite-force levels. This means that individuals with thin masticatory muscles could belong to either the long-face or the normal group, whereas scarcely any individual with thick masticatory muscles could be found in the long-face group. The finding that individuals with strong masticatory muscles have a more homogeneous facial morphology than individuals with weak masticatory muscles lends support to this explanation.[104] Thus, it may be concluded that the masticatory muscles are able to influence craniofacial growth of man provided that the tension they apply to the facial bone structures is above a

FOR AUTHOR USE ONLY

certain threshold, reaching what Frost calls “the mild overload window.” The principle that is valid for long bones, that “modeling drifts can adapt bone to overloads by changing bone architecture and adding bone, but apparently cannot adapt it to low loads or disuse could be also applied to the craniofacial complex.[105] Thus, the epigenetic influence of the masticatory muscle forces on craniofacial growth may only apply in the presence of increased muscle activity but not necessarily with decreased muscle activity.

Introduction

Masticatory muscles are anatomically and functionally complex in all mammals, but relative sizes, orientation of action lines, and fascial subdivisions vary greatly among different species in association with their particular patterns of occlusion and jaw movement. Although mastication is a hallmark attribute of mammals, there is great diversity of all its components. Ignoring specialised feeding systems such as those of whales and anteaters, this discussion will concentrate on typical mastication, addressing differences among species commonly used in research. Masticatory muscle activation and coordination determine the direction of jaw movement, control occlusal force, and deform the skull in a variety of ways. The critical features to understand them are action line, force production, and relationship to the cranium. Action line and force production are not as straightforward in the complicated masticatory muscles as in limb muscles, which tend to be arranged more linearly. Similar difficulties with the irregularly shaped skull make the effect of muscles on the bones challenging to model. Thus, this short review will emphasise empirical data from electromyography (EMG) and in vivo recordings of bone strain.

FOR AUTHOR USE ONLY

Complicated muscles

One feature in common among mammals is the size and complexity of the muscles of mastication, which occupy much of the head. In terms of size, it is customary to examine the relative mass of individual jaw muscles as a percentage of the whole. This procedure illuminates the contrast between species whose

masticatory apparatus is dominated by the temporalis muscle (typically generalised species and specialized carnivores with a hinge-like TMJ like cats) and those that emphasise the masseter and medial pterygoid (typically omnivores like primates or herbivores like rabbits, with anteroposterior mobility of the TMJ). However, standardizing each muscle mass to the total masticatory mass obscures whether there are differences in the relative size of the total masticatory mass relative to head size, which remains an unanswered question. Although the same basic terminology (e.g., ''masseter'' and ''lateral pterygoid'') is used for all mammals, it is important to realise that these names are based on bony attachment areas and not on function. The anteriorly directed, fascially subdivided superficial masseter muscle of rodents has little functional resemblance to its relatively vertical and unitary human counterpart.

The jaw muscles have broadly distributed origins and insertions on the skull and mandible, but the main factor that contributes to functional complexity is the fact that most muscle fibers attach to internal aponeuroses rather than to the bones directly. Necessarily, fibers that attach to different surfaces of an aponeurosis must have different orientations, raising the possibility that differential contraction of fibers could change the direction of muscle pull, a possibility that has been confirmed in a variety of masticatory muscles. Thus, action line is not a constant, but varies dynamically throughout a masticatory cycle. Distortion of aponeuroses from stretching or folding could alter fiber direction evenmore, but results from one muscle, the pig masseter, indicate that aponeurotic stretching is limited to no more than about 5% linear strain.

Muscles and movements

Both the muscles and the dentition are determinants of the direction of the power stroke. Teeth play a larger role when they provide an inclined plane, keeping the direction of jaw movement medial even if the muscle resultant is vertical or slightly lateral. Examples include rabbits. Muscles become more significant when irregular occlusal surfaces do not define a plane, i.e., the low-cuspedmolars of pigs. Age changes in power stroke are independent of occlusal development in pigs but may relate to muscle vectors. Muscle anatomy both causes and reflects jaw movement. Muscles (or parts of muscles) may be mostly rotatory (open/ close) or mostly translatory (anterior/posterior or medial/ lateral). The relative importance of upward, medial, and anterior components in the power stroke is associated with startlingly different muscle anatomy. Thus, we can explain why the lateral pterygoid is small and unimportant in carnivorans such as cats and ferrets but huge in humans, and why the masseter of rodents is specialised and subdivided. There are some surprises. Parts of the medial pterygoid and/or masseter in several species open the jaw rather than closing it, raising some interesting questions about neural circuitry .Most mammalswith transverse masticatory excursions use a combination of muscles referred to as either ‘‘couples’’‘triplets’’ consisting of the superficial masseter and medial pterygoid of one side and the temporalis of the opposite side, with the jaw moving toward the temporalis side. This reflects the fact that the temporalis-side condyle moves posteriorly relative to the masseter-side condyle, i.e. the movement is a rotation.

FOR AUTHOR USE ONLY

The deep masseter, which typically has a posterior vector, usually acts with the temporalis rather than the superficial masseter ‘‘zygomaticomandibularis’’ and is often called.

Muscles, mastication and the biomechanics of the skull Masticatory muscles, through their direct action on bony attachments and their indirect action in loading the teeth and the jaw joints, constitute the major biomechanical challenge to the skull. Direct effects of a muscle attachment are sensitive to the particular muscles used and to the pattern of muscle coordination. For example, the temporalis and masseter twist the pig braincase in opposite directions, and because these muscles usually act in opposite-side ‘‘couples’’, the effect is exaggerated rather than cancelled. Indirect effects depend on global features such as total muscle force and the particular teeth in occlusion. With regard to total muscle force, the point is simply that the muscles collide the mandible with the upper jaw and thus engender reaction forces at points of contact, specifically the teeth and the TMJs. The former is occlusal force, and its major influence on the skull is to shear the maxilla upward and the mandible downward. The reaction force on the TMJs arises from lever mechanics and the fact that the resultant muscle force rarely if ever passes through the bite point. Depending on the particular species, however, it is clear that there are major differences in the geometry of the muscle resultant and hence the relative magnitude of the TMJ reaction load. For deformation of the skull, an important determination is whether occlusion is unilateral or bilateral. Many mammals have

FOR AUTHOR USE ONLY

jaws so anisognathous that only one side at a time can be in molar occlusion. Strain gage readings from the mandible and braincase are highly asymmetrical during chewing in such animals. For example, working and balancing mandibular bodies show opposite directions of bending because of the influence of the unilateral bite point. Other groups, including many rodents, pigs, and higher primates, have some probability of occlusal contact occurring on the balancing side, and may even have a bilateral bolus and true bilateral chewing. Thus, in pigs, mandibular and maxillary strains are identical on the working and balancing sides. In fact, the only part of the pig skull that strains differently depending on the side of chewing is the premaxillary, because incisor occlusion, unlike molar occlusion, is one-sided. Like occlusal force, TMJ loads are reactions to muscle pull. The balance between occlusal and joint force is a product of muscle anatomy and contraction pattern. In pigs, with bilateral occlusion and similar magnitudes of EMG on the two sides, bone strains at the TMJ are symmetrical. In contrast, mammals with anisognathous occlusion are expected to have heavier loading on the balancing side. A final location of interest is the mandibular symphysis. An unfused symphysis is the primitive condition and can act either as a facilitator of unilateral occlusion or as the means by which a bilateral occlusion can be maintained throughout the duration of the power stroke. Symphyseal fusion has been independently acquired in a number of lineages, including that leading to humans, and is associated with the timing and level of recruitment of the balancing side muscles. Like higher primates, pigs have strong recruitment of balancing side muscles as part of the force couple mechanism for moving the

FOR AUTHOR USE ONLY

mandible laterally. The pig symphysis begins to ossify at about the time ofcomplete weaning. Strains recorded from the unfused symphysis are large, generally similar in magnitude to those from unfused sutures. After fusion begins,strain magnitudes drop to the same level as typically seen for solid bones. During jaw opening the pattern of deformation is generally consistent with medial transverse bending, which has also been reported in macaques and humans. This deformation is attributed to the medial pull of the lateral pterygoid muscles. However, during closing the pattern of strain reveals a tendency of themandibular bodies to rotate around their long axes. This may be a direct effect of muscle contraction, particularly the rotational forces arising from the masseter.

How does the masticatory system cope with loss of a muscle?

The choreographed interplay within and between the complicated masticatory muscles focuses attention on whether, and how, mastication would be changed if one muscle or even just one muscle compartment were incapacitated. This question might seem arcane, because most neuromuscular diseases attack indiscriminately and would not target single muscles. However, it is increasingly common these days for patients to have single muscles paralysed, not only for therapeutic, but also for cosmetic reasons. To some extent, the answer depends onwhich muscle and species. The loss of one masseter may be less of a problem for those taxa in which the inclined planes of the teeth guide the power stroke (suchas rabbits) than for those that depend on muscle choreography (such as pigs). In order to maintain occlusal force, however, all species should increase the

FOR AUTHOR USE ONLY

recruitment level of synergists. Muscle weights suggest that the unparalysed masseter in rabbits hypertrophies. The short-term pig experiment showed tha tthe masseter's synergists for transverse movements, the ipsilateral pterygoids and the contralateral temporalis, were overactive, a prelude to hypertrophy.

It is also likely that such changes in muscle usage would alter skull loading. Both the masseter and medial pterygoid create similar strain magnitudes on the pig mandibular condyle, but the orientation of strain is unique for each muscle. Therefore, if one masseter were incapacitated, total joint load would not only be reduced, but also re-oriented. If such conditions were long maintained, as for example with botulinum toxin, bony adaptations would be likely. The growing rabbits in the study by Matic developed smaller condyles on the paralysed side, presumably because of decreased loading. Preliminary data on adult rabbits suggest that bone strain in the condyle is indeed reduced by paralysis of the ipsilateral masseter, and that this unloading leads to massive bone loss in the condyle.

FOR AUTHOR USE ONLY

Our goal in preparing this review has been to highlight the classification, embryonic origin, differentiation and myogenesis, as well as the role of craniofacial muscles in growth of the craniofacial skeleton. The relationship of various craniofacial muscles in different growth patterns and it effect on orthodontic treatment has also been discussed.

The induction, differentiation, and morphogenesis of craniofacial muscles is a fertile and relatively untouched area for multifaceted experimentation with acascades of signaling cascades and regulatory genes that specify each group of craniofacial muscles. Various regulatory factors like Myf5, MyoD, Pax3, Pax7, Pitx2, Tbx1, Musculin and Tcf21 play a vital role in craniofacial muscle embryogenesis and morphogenesis. The challenges that lie ahead will be to precisely the signals that regulate the dynamic developmental processes underlying the specification, migration and differentiation of the different myogenic lineages in the head.

The relationship between the mandibular muscles and craniofacial morphology would seem to confirm the ever-present but still elusive relationship between form and function. A general consensus of the studies on the relationship between mandibular muscles and head dimensions is that subjects with strong or thick mandibular muscles have wider transverse craniofacial dimensions. In addition, tendencies toward parallelism between the jaw bases and between the occlusal and mandibular lines, as well as small gonial angles and smaller lower anterior facial height have also been noted. Although it is widely accepted that

FOR AUTHOR USE ONLY

dolichofacial patients have relatively weak mandibular muscles compared with brachyfacials, it is still not known whether the strength of the mandibular musclesdetermines craniofacial morphology or vice versa. Bite-force differences between brachyfacial and dolichofacial subjects have been claimed to be related to the strength or the mechanical advantage of the mandibular muscles.

The effects of the mandibular muscles associated with different types of tooth movements should be considered during orthodontic treatment planning. The choice of treatment mechanics, the timing of treatment, and any extraction decision might well be quite different for different underlying vertical patterns, even for the management of similar occlusions. Subjects at either extreme of the vertical facial spectrum are likely to pose the greatest challenges to the orthodontist during treatment.

It was found that there was no significant effect of the masticatory hypofunction on the cranial growth and development in the growing rats but that masticatory hypofunction affected the growth and development of the maxillofacial skeleton. The regions where statistically significant changes were found because of masticatory hypofunction are as follows: total skull length, total anterior face height, lower anterior face height, ramus mandibular height, corpus mandibular height, premaxillary length, and maxillary width were reduced, but foramen incisivum width was increased.

FOR AUTHOR USE ONLY

Muscle action and skull biomechanics are inextricably intertwined. In the evolutionary sense, the muscles of mastication are co-adapted with dental morphology and jaw movements to produce species-specific chewing patterns. In

the physiological sense, masticatory muscles comprise the major loading on theskull, influencing its growth and controlling its strength.

Craniofacial growth has been of keen interest to anatomist,physiologist,endocrinologist,orthodontist, physician and many more. This book is a summary of various theories of craniofacial growth which includes Genetic theory, Sutural theory, Cartilagenous theory, Functional matrix theory, van Limborgs theory and Servosystem theory. No single theory is acceptable and a combination of all these theories help in better understanding of the complex nature of craniofacial growth and development.

Dr Alok Ranjan, currently Assistant Professor at Bharati Vidyapeeth Dental College, Pune has completed his Masters in Dental Surgery, Orthodontics in 2019. He has a keen interest in publications and research and has numerous publications to his credit.

Introduction

Conceptual terms Growth, Development, Maturation are synonymously used sometimes but they actually mean different.

Growth may be defined as the normal changes in the amount of the living substance. Growth is quantitative aspect of biologic development and is measured in units of increase per unit of time. Growth is the result of biologic processes by means of which living matter normally gets larger. It may be the direct result of cell division or the indirect product of biologic activity, for example bones and teeth.

We equate growth with enlargement, but there are instances in which growth result in a normal decrease in size, for example the thymus gland after puberty. Growth emphasizes the normal dimensional changes during development. Growth may result in increase or decrease in size, change in form or proportion, complexity, texture.

FOR AUTHOR USE ONLY

Growth and development indispensable in orthodontics and dentofacial orthopedics because

- A conscientious practitioner should be able to manipulate facial growth for the benefit of the patient.
- It is important first to understand what is normal variation, and then the pathologic process.
- To understand the development of conditions observed in adults.

Definitions

Growth

According to **Meredith:**

Growth is the entire series of sequential anatomic and physiologic changes taking place from the beginning of prenatal life to the close of senility.

According to **Krogman:**

Growth is the increase in size, change in proportion and progressive complexity.

FOR AUTHOR USE ONLY

According to **Huxley:**

Growth may be defined as the self multiplication of living substance.

According to **Moss:**

Change in any morphological parameter which is measurable.

According to **Moyers:**

Quantitative aspect of biological development per unit of time.

According to **Todd:**

Growth is increase in size of an organism.

According to **Salzmann:**

Growth is a physio – chemical process by which an organism becomes larger.

According to **Scott:**
Growth is three fold process in which cell multiplication, differentiation and organization takes place

According to **Webster:**
Growth is defined as progressive development (i.e. evolution, emergence, increase, or expansion)

Development

FOR AUTHOR USE ONLY

According to **TODD:**
Development means progress towards maturity.

According to **MOYERS:**
All the naturally occurring unidirectional changes in the life of an individual from its existence as a single cell to its elaboration as a multifunctional unit terminating in death.

According to **PROFIT:**
Development connotes an increase degree of organization, often with unfortunate consequences for the natural environment.

According to **WEBSTER:**
Development is defined as going through natural growth, differentiation or evolution by successive changes.

According to **ENLOW:**

Facial growth and development is a morphogenic process working towards a composite state of aggregate structural and functional balance among all of the multiple, regional growing and changing hard and soft tissue parts.

Maturation

According to **MOYERS:**

Maturation means ripening the stabilization of adult state brought about by growth and development.

FOR AUTHOR USE ONLY

According to **WEBSTER:**

Emergence of personal characteristics and behavioral phenomena through growth process.

The changes associated with ageing that is degeneration and senility is considered some as a part of maturation, while other consider it as a part of development. Still other considers these changes as a part of development and maturation.

Conclusion

Growth is largely an anatomic phenomena, whereas, development is physiological and behavioral.

Development is increased specialization at the loss of potential.

Basic Tenets of Growth

Pattern:

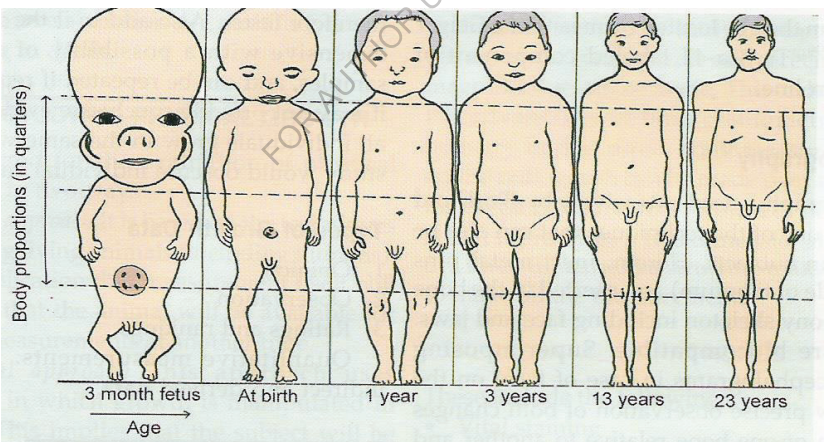
It reflects proportionality, usually of a complex set of proportions and change in these proportional relationships over time. In other words, the physical arrangement of the human body at any one time is a pattern of specially proportioned parts. Important aspect of pattern is its predictability i.e pattern repeats. The only difference between the geometric pattern and growth pattern is time dimension.

Cephalo-caudal gradient:

This simply means, there is an axis of increased growth extending from the head towards the feet.

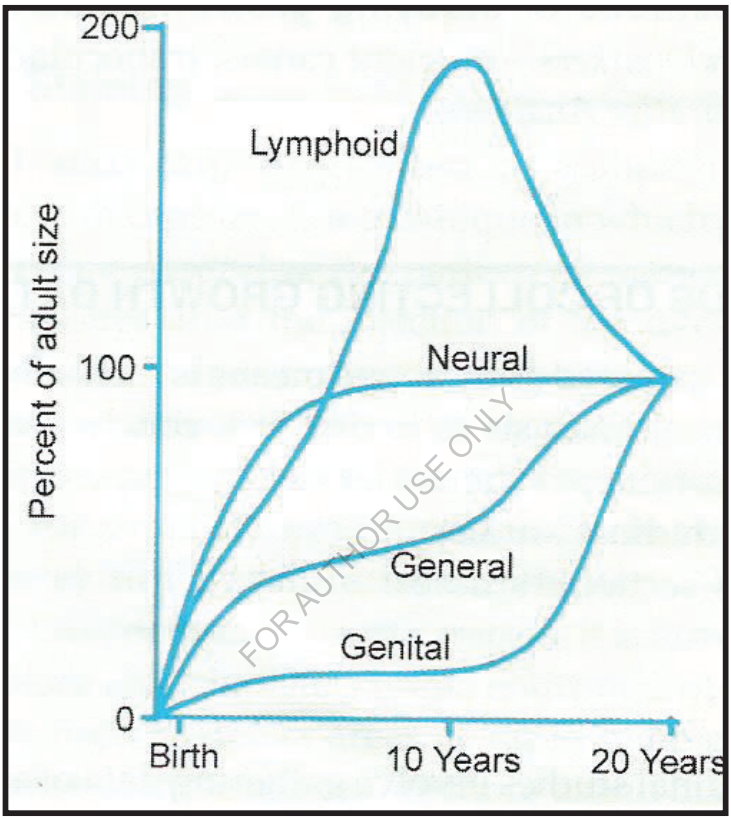
Fig. 1

FOR AUTHOR USE ONLY



Scammon's Growth Curve:

Fig. 2



FOR AUTHOR USE ONLY

The neurocranium follows the neural curve of growth. The lower face or splanchnocranium approximates the general or bodily growth curve. Thus for a particular age there is a difference in the total growth accomplished. By differential growth, the face emerges from beneath the cranium. The upper face under the cranial base influence moves upwards and forwards and the lower face moves forwards and downwards on an

expanding “V” principle. This divergent pattern permits vertical growth through tooth eruption and alveolar bone growth.

Table 1

Years	Cranium	Upper face	Lower face
o-5	85%	45%	35%
5-10	96%	65%	40%
10-20	Total	Total	65%

Significance of Scammon’s growth curve:

-Neural tissue grows early indicating neurotrophism or inductive influence of neural tissues on other tissues.

FOR AUTHOR USE ONLY

-Negative growth shown by lymphoid tissue indicating regression of lymph organs after age of 10 years.

-‘s’ shaped general curve indicating change in velocity of growth.

-Steep increase in genital curve indicating puberty and maturation.

Variability

It can be difficult, but clinically very important, to decide whether an individual is merely at the extreme of normal variation or falls outside the normal range. It is important to express variability quantitatively. One way to do this is to evaluate a given child relative to peers on a standard growth chart. Variability may be because of illness or timings.

Timings

The biologic clocks of different individuals are set differently. Variation in timings arises because the same event happens for different individuals at different times.

Growth does not take place at the same rate through out life that is not at all times systems of body grow at same rate. There are certain periods when there is sudden acceleration of growth due to activation of more growth center. This sudden acceleration of growth is called as growth spurt.

All children undergo a spurt of growth at adolescence but the growth spurt occurs at different times in different individuals.

Classification of growth spurt:

PRENATAL:

In Prenatal life growth spurts occurs just before birth.

FOR AUTHOR USE ONLY

POSTNATAL:

First peak: Greatest increment of growth occurs during third year age level.

Second peak: Pre pubertal, which is many times 6-7 years in female, 7-9 years in male.

Third peak: Pubertal, this is variable 10-12 years in female, 13-15 years in male. It occurs earlier and fro shorter duration in females but in boys it occurs at later age and is of long duration.

Growth spurt at adolescence can be seen more clearly by plotting a curve indicating change in height or weight and the resultant curve obtained is called as distance curve and acceleration and deceleration of the rate in the growth is indicated by velocity curve.

Girls Duration 3.5 years

Stage 1 Beginning of adolescent growth.	Appearance of breast buds, initial pubic hair.
Stage 2 Peak height in velocity (about 12 months later)	Noticeable breast development, axillary hair, more abundant pubic hair
Stage 3 Growth Spurt ending (12-18 months later)	Menses, broadening of hips with adult fat distribution, breasts completed

Boys Duration – 5 years

Stage 1 Beginning of adolescent growth	"Fat Spurt" weight gain, Feminine fat distribution
Stage 2 Height Spurt beginning (about 12 months later)	Redistribution in fat, pubic hair, growth of penis.
Stage 3 Peak velocity in height (8-12 months later)	Facial hair appears on upper lip only, axillary hair, muscular growth with harder and more angular body form
Stage 4 Growth Spurt ending (15-24 months later)	Facial hair on chin and lip, adult distribution of pubic and axillary hair, adult body form

FOR AUTHOR USE ONLY

SIGNIFICANCE OF GROWTH SPURTS

Malocclusion can be treated during growth spurts taking advantage of active growth period. Arch expansion and rapid maxillary can be undertaken during period of maximum growth.

Malocclusion requiring surgical correction is to be undertaken after growth spurt is complete.

Growth modification of jaws can be done during growth spurts.

Before growth spurts are seen dental corrections can be undertaken by use of myofunctional appliances.

Growth spurts are obvious for orthopedic correction of maxillomandibular mal-relationship.

Growth spurt period is the best time for interceptive orthodontic treatment e.g. Treatment of class 2 malocclusion using activator therapy. Treatment of class 3 malocclusion using headgears.

Very few girls show mixed dentition growth spurts. Thus mixed dentition jaw changes are more likely to succeed in boys.

FOR AUTHOR USE ONLY

Different kinds of growth that can be identified

- Size change
- Positional change
- Proportional change
- Functional change
- Maturational change
- Compositional change

STRUCTURE	FETUS	NEWBORN	ADULT
Skin & Fat	16%	26%	25%
Viscera	16%	16%	11%
Nervous System	21%	15%	03%
Muscle	25%	25%	43%
Skeleton	22%	18%	18%

During post-natal growth, there is 17% decrease in total body water. Protein & Fat both increase by about 40%. Minerals increase by nearly 250%.

- Timing and sequential change
- Physiological change

FOR AUTHOR USE ONLY

Types of Growth

Cellular Types:

- Hyperplasia
- Hypertrophy
- Increase in intercellular matrix

Soft – Tissue Growth

- Interstitial growth: Process go on everywhere within the tissue, Combination of hyperplasia and hypertrophy. Secretion of extra cellular material can also accompany interstitial growth but hyperplasia primarily and hypertrophy secondarily are its characteristics.

FOR AUTHOR USE ONLY

Skeletal growth

- Direct / surface apposition: Formation of new cells occurs in periosteum, and extra-cellular material secreted there is mineralized and becomes new bone.
- Interstitial growth:is a prominent aspect of overall skeletal growth because a major portion of skeletal system is originally molded in cartilage. Hypertrophy occurs in number of special circumstances but is a less important mechanism than hyperplasia in most instances.

Histological growth

Characteristics	Cartilage (endochondral)	Bone (intramembranous)
Calcification	Non calcified	Calcified
Vascularity	Non vascular	Vascular

Surface membrane	Non essential	Essential
Rigidity	Flexible	Inflexible
Pressure resistance	Tolerant to pressure	Sensitive to pressure

FOR AUTHOR USE ONLY

Terminologies related to growth

Growth fields:

The outer and inner surfaces of bones are blanked by mosaic like pattern of soft tissue, cartilage or periosteum.

Growth field is responsible for bone enlargement and consists of remodeling and displacement.

Growth Site

Some growth fields have traditionally been signaled out for special attention. These special growth sites include the sutures of face and cranium, maxillary tuberosity, and alveolar bone. This site does not carry out the entire growth process but all other inner and outer surfaces of given bone also actively participate in the overall growth.

FOR AUTHOR USE ONLY

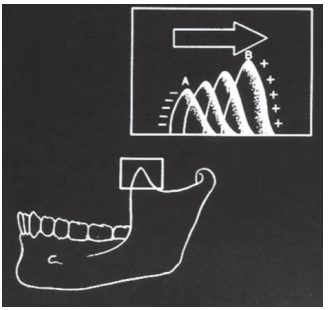
Growth Centre

Growth center having intrinsic growth potential, tissue separating force, and essentially endochondral in type Baume. Zone of growing cartilage that expands by swelling in particular plane are spoken of as dissuasion fields Baume1957. Cartilage by the virtue of its interstitial growth, turgidity and resistance to deforming forces can separate growing bone at sutures just as brain or eye ball can scott,1967 This growth centre concept has come into disfavor however, because it is now believed that such centers do not control the growth process, as they are not master centers.

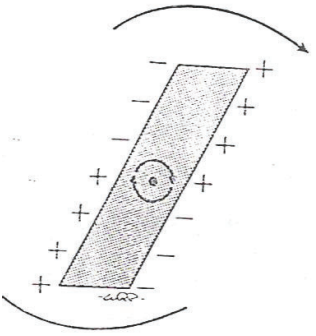
No part is developmentally independent and self contained; this is a fundamental and very important principle of growth -Enlow.

Growth Remodeling

Differential Growth activity involving simultaneous deposition (+) and resorption (-) of all inner and outer surfaces of bone.



Rotational Remodeling



FOR AUTHOR USE ONLY

Types of Remodeling

- Biochemical Remodeling
- Secondary reconstruction of bone by haversian system

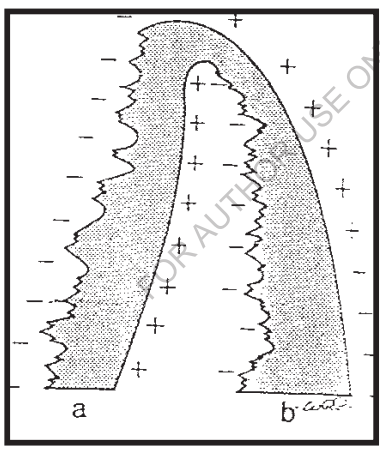
- Remodeling following disease and trauma
- Growth Remodeling

Growth movements

Growth movement occurring towards depository surface by combination of deposition and resorption. About half the total amount of cortical bone tissue is of endosteal origin and about half of periosteal origin.

Primary displacement:

The process of physical carry takes place in conjunction with bones own enlargement. The respective direction of growth and movement is always opposite.

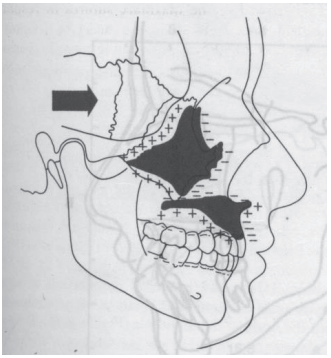


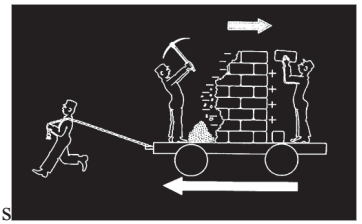
FOR AUTHOR USE ONLY

Secondary Displacement:

In secondary displacement the movement of the bone is not directly related to its own enlargement.

"Domino" effect – growth changes get passed on from region to region to produce secondary effect in areas quite distant. Such changes are cumulative.





s

FOR AUTHOR USE ONLY

Although these growth movements are carried out by osteogenic membranes and cartilages, the bone contributes feedback information to them so that when size, shape, biochemical properties, and so forth, of the bone comes into equilibrium with functional requirements the histogenic activity then becomes turned off. - Enlow

Relocation

The relocation function of remodeling. Remodeling is the process of reshaping and resizing each level within a growing bone as it is relocated sequentially into a succession of new levels. E.g. Nasal floor & Mandibular ramus.

Methods of growth assessment

I)Direct:

Measure mental Approach (Craniometry, Anthropometry)

Experimental Approach (Vital Staining, Implant studies, Histological Studies, Histochemical studies)

II)Indirect:

Measure mental Approach (Serial cephalometry, Impression casts, photographs Serial radiographs & Implants)

Experimental Approach (Radioautograph)

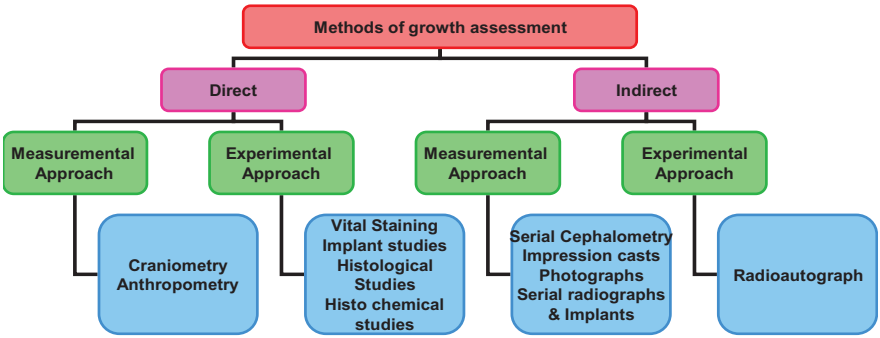
a) MEASUREMENTAL APPROACHES:

Are based on techniques for measuring living animals including humans with the implication that the measurement itself does no harm and that the animal be available for additional measurements at another time.

b) EXPERIMENTAL APPROACHES:

Uses experiments in which growth is studied in more detail but it may be destructive so such experimental studies prefer to restrict non human species.

FOR AUTHOR USE ONLY



-Dixon

Other methods

- Digital subtraction radiography.
- Computerized tomography.
- Magnetic resonance imaging.
- Sonic interferometry.

FOR AUTHOR USE ONLY

Newer method:

- Bi-orthogonal grids elliptical Fourier function and finite element.

1) CRANIOMETRY:

This is based measurements of skull found among human skeleton remains. It was originally used to study the skull of Neanderthal and Cro-Magnon people. Growth pattern is ascertained by comparing one skull to another. ADVANTAGE: Precise measurements can be made on dry skull.

DISADVANTAGE: All these growths must be cross-sectional means that all though different are represented in population; same individual can be measured at only point in time.

II) ANTHROPOMETRY:

By anthropometry, it is possible to measure skeletal dimension on living organism. Various landmarks established in studies of dry skulls are measured in living individuals by using soft tissue points overlying these bony landmarks.

ADVANTAGE:

It is possible to follow up the growth of an individual directly, making the same measurements repeatedly at different times. This gives longitudinal data that is repeated measurements on the same individual.

DISADVANTAGE:

The result would be different because of soft tissue thickness overlying the landmarks.

FOR AUTHOR USE ONLY

III) CEPHALOMETRIC RADIOLOGY:

Introduced by Broadbent in the United States and Hoffrath in Germany in 1931. This technique depends on precisely orienting the head before radiograph is made with precisely controlled magnification.

ADVANTAGE:

This approach can combine the advantages of Craniometry and Anthropometry. It allows a direct measurement of bony skeletal dimensions,

since bone through seen through the soft tissue covering in the radiograph and it also allows the same individual to be followed over time.

DISADVANTAGE:

It produces a two dimensional representation of a three dimensional structure, so even with precise head positioning, not all the measurements are possible. But this can be overcome by making more than one radiograph at different orientation and using different angulations to calculate oblique distances.

Cephalometry has made possible standardization of the serial studies of living growing craniofacial skeleton and associated features used for the study of facial growth, orthodontic diagnosis, treatment planning and assessment of therapeutic results.

FOR AUTHOR USE ONLY

IV) VITAL STAINING:

Belchier in 1736 reported that bones of animal which have been eaten the matter plant were stained red colored. John Hunter in 18th century discovered that the active agent was a dye called alizarin. Alizarin reacts strongly with calcium at sites where bone calcification is occurring and thus marks the location where active growth was occurring.

Dyes used are:

- Alizarin red 5
- Acid Alizarin blue
- Trypon blue
- Tetracycline
- Lead acetate
- Procion dyes
- Fluorocrom

- Sodium fluoride

Tetracycline used as vital bone marker. It binds to calcium at the growth sites. The major disadvantage of Tetracycline is the discoloration of teeth. Lines formed by vital dyes become colored as a subsequent bone growth occurs. Vital dyes stain only that bone which is actively being laid down during the period in which the dye is in the blood stream. Thus the thin colored line on the bone is seen and subsequently formed bone deposits are not colored.

ADVANTAGES:

This method of studying bone growth reveals the manner in which bone is laid down, the sites of growth, the direction of growth and relative duration at different sites and timings of growth.

DISADVANTAGES:

It does not provide direct evidence of bone resorption.

FOR AUTHOR USE ONLY

V) RADIOISOTOPES:

Radioisotopes of certain elements or compounds often are used as in vivo markers for studying bone growth; such labeled material is injected and then after a time, located within the growing bones by means of Geiger counters by the use of auto radiographic techniques. In auto radiographic techniques, the bones or sections of bones are placed against photographic emulsions that are exposed by emission of radioactive substance.

Radioisotopes used are:

- Calcium 45
- Phosphorous 32
- Technetium 33

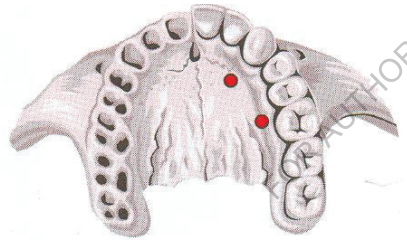
VI) IMPLANTS:

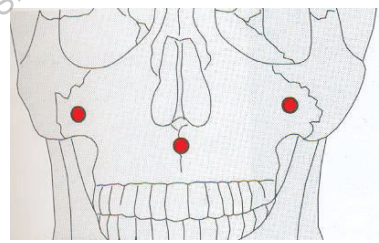
Bjork has devised an ingenious method of implanting tiny bits of Tantalum into growing bones of animal or human being. These serve as reference markers during serial cephalometric analysis and allow precise observations of both changes in the position of one bone related to another and change in the external contour of individual bones.

Following are sites for implantation:

In Maxilla:

- Hard palate behind deciduous canine.
- Below anterior nasal spine.
- Two implants on either side of zygomatic process of maxilla.
- Border between hard palate and alveolar process medial to 1st molar.





FOR AUTHOR USE ONLY

In Mandible:

- Midline below root tips.
- Two pins on either side of mandibular body, one pin below 1st premolar and other below 2nd premolar.
- On the ramus in level with occlusal surface of molars.

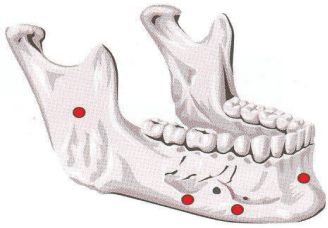


Table 6.2 Approximate Information Obtained from Various Methods Used to Study Postnatal Bone Growth

Method	Growth				Type of Study	Limitations
	Site	Amount	Rate	Direction		
Direct Measurements						
Osteometry						
Skeletal remains – craniometry	0	X	X	X	Cross-sectional	Material of unknown history, posthumous distortion
Living – Anthropometry	0	X	X	X	Longitudinal	Soft tissues restrict accurate measurement
Vital Staining[1]	XXX	XXX	XX	X	Longitudinal	Toxicity, method requires refinement
Implant markers[1,2]	XX	XXX	X	X	Longitudinal	Local reaction to implants, requires reoperation
Histological and histochemical methods	XXXX	X	0	X	Cross-sectional	Sections show conditions at time of death of tissue only
Indirect Measurements						
Impressions and casts	0	XX	XX	XX	Longitudinal	Soft tissues restrict accuracy of impression
Photographs	0	X	X	X	Longitudinal	Two-dimensional study of three dimensional process
Serial radiography	0	XXX	XX	XX	Longitudinal	Must obtain stable landmarks, three-dimensional information not entirely accurate, radiation exposure
Measurements in Combination						
Serial radiography and implantation[1,2]	XXX	XXX	XXX	XXX	Longitudinal	Three-dimensional information not entirely accurate, radiation exposure
Serial radiography and metaphyseal bands[3]	XXX	XXX	XXX	XXX	Longitudinal	Record of a toxic process, rate of growth not normal, radiation exposure
Radioautographs	XXX	0	0	0	Cross-sectional	Primarily of qualitative value

Note: 0, Gives no information; X, shows trends; XX, relatively accurate; XXX, grossly accurate; XXXX, microscopically accurate. Can be used to measure:

[1] sutural growth
[2] apposition and resorption
[3] endochondral growth

FOR AUTHOR USE ONLY

Types of Growth Data

- Opinion: at the best it is the cleaver guess based on experience. It is crudest form of scientific knowledge. They should be always being designated for what they are – one persons biased guess.
- Observations: useful in studying "all or non law". Used in limited way when quantification of data is not possible.
- Rating and ranking: data difficult to quantify and thus compared to conventional rating scales.
- Quantitative measurements: minimum mis-understanding and permits testing of hypothesis by other workers.

  Direct: measurements on living persons by means of measuring devices.

Indirect: measurements taken from images or reproduction of the actual persons. Eg.cast, photocopy.

Derived: comparison of at least two other measurements.

FOR AUTHOR USE ONLY

Growth Data Collection

Cross Sectional / Prevalence Studies

- Simplest form of observational study.
- Single examination of cross section of population at one point in time.
- Results can project whole population provided sampling has been correct.
- But, average tends to obscure individual variation
- Usually for chronic diseases

Longitudinal Studies

- Repeated observations in the same population over a prolonged period of time, difficult to organize, time consuming, risk of losing subjects.
- Valuable information than the cross sectional studies
- Useful to study natural history of disease, future outcome, risk factors, and incidence.

FOR AUTHOR USE ONLY

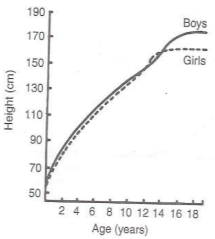
Semi Longitudinal Studies

- It is a combination of cross sectional and longitudinal types.
- Subjects at different age levels are seen longitudinally for shorter periods.

Graphic Interpretation of Growth Data

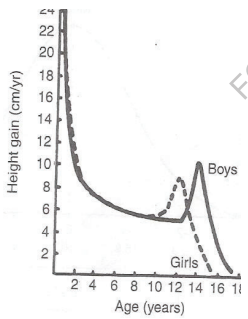
Distant curve/cumulative curve –

- Data can be derived from cross – sectional and longitudinal studies indicates distance a child has traveled along the growth path.



Velocity Curve/Incremental curve –

- Rate of growth of child is indicative that data is derived from longitudinal studies.



FOR AUTHOR USE ONLY

Factors Affecting Growth

- Heredity
- Evolution
- Nutrition
- Illness
- Race(ethnic)
- Family size and birth orders
- Secular trends
- Circadian and seasonal effects
- Psychological disturbances
- Hormones
- Teratogens
- Neuromuscular functions
- Masticatory function
- Orthodontic treatment

FOR AUTHOR USE ONLY

Heredity

- Progeny resembles one or both parents is often apparent.
- The primary basis for the similarity of MZ twins is genetic.
- These are probably primary control for initiation and formation.
- There are structural, modifier(regulator), oncogenes, orthogenes, pseudogenes, provirus genes and so on.
- Copy of all the genes is present in every cell but only the parts needed are used by that cell. (Beardsley,1988)
- Regulatory genes - homeotic genes
- Homeoboxes - short sequence of DNA

- Homeotic - like genes -Slavkin.
- Control hierarchy -Beardsley.
- Local feed back and intercommunication
  -adhesion molecules
  -humoral chemicals
  -gap junctions
- Genes for the muscles have a modifying effect on the bone.
- Thus what is environmental to the bone is genetic to the muscle.
- The correlation between upper and lower tooth size is 0.8 - Moorrees and Reed,1964

Conclusion

- Craniofacial growth have polygenic inheritance, continuous distribution of variable and it is agreed that environment changes all size components, at least in face.
- Parent can explain only 25% of size variation in faces of progeny.
- Even if mandibular size is inherited in the mendelian fashion, it is masked by environmental influence.

FOR AUTHOR USE ONLY

Evolution

- Verticalization and cerabralization.
- Enormous enlargement of the brain have caused a "flexure" of human cranial base.
- Changes in the eye position.
- Rotation of the olfactory bulb and the nasomaxillary complex.
- Rectangular maxilla than the triangular in other mammalians.

- Control of the blood flow in the dermis, combined with sweat gland activity, provide equivalent for nasal thermoregulation.
- Evolutionary pressure on third molars-this is not the way evolution works, you have to die because of third molars before reproducing for there to be any evolutionary pressure.
- Evidence suggest that, within limits we have larger jaws than our ancestors 200 years ago. Teeth are getting larger.

-Garn et al, 1968.

FOR AUTHOR USE ONLY

Nutrition

- Nutritional deprivation in utero may result in permanent retardation of growth.
- Significant Nutritional deprivation at the puberty exerts similar growth retardation effect.
- Nutritional deprivation at the other times in childhood dose not produce permanent impair linear growth potential.("catch up")
- Protein rich diet delays the onset of sexual maturity.
- Nine essential amino acids for growth.
- Calcium, phosphorous, magnesium and fluoride are essential for bones and teeth.
- Iron for hemoglobin.
- Vitamin A controls activity of both osteoblast and osteoclast.
- Vitamin C necessary for bone & connective tissue growth.
- Vitamin D for normal bone growth.

- Oxygen is also essential component of the normal growth.

Chronic Illness

- Skeletal growth occurs when all other body requirements have been met.
- Chronic illness alters this balance, leaving less of total energy available to support growth.
- Chronically ill patient fall behind that of the normal child in growth. Effect is cumulative.
- Females compensate better than the male following illness.
- Hormonal changes are responsible for growth changes observed in chronically ill patient.

FOR AUTHOR USE ONLY

Race (ethnicity)

- No race represents a single, homologous grouping, but, rather a composite assemblage of many geographically, environmentally, and morphologically diverse subgroups.
- White people have convex profile, Blacks have bimaxillary prognathic or concave profile, and Indians are in between these two.

Family size and Birth orders

- First born babies have less weight, small stature but high IQ.
- Smaller the family better would be nutrition & other conditions.

Secular Trends

It is any change in size shape or timing that is consistent in direction over several generation or successive period of time –Garn1987

- Increased growth velocity.
- Increased final adult height.
- Earlier maturation.
- Causes:-improved nutrition

-improved health status

-decreased mortality

- Out breeding seems to be the most commonly mentioned genetic factor.
- Heterosis - demographic changes had an effect on stature by genetic phenomena.

-Tanner1978.

Males have broader faces and females have longer faces.

FOR AUTHOR USE ONLY

Circadian and Seasonal variation

- Growth in height faster in spring.
- Growth in weight faster in autumn.
- Seasonal variations have shown to affect adipose tissue content and weight gain in new born.
- Growth in height and eruption of teeth is greater at night because of hormonal changes.

Psychological disturbances

- Maternal deprivation syndrome
- Cultural factors-psychological abuse.

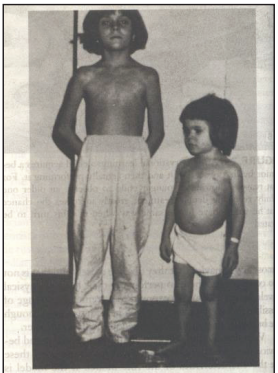


FIGURE 2-49 Both these girls are 7 years old. The one on left is normal, whereas the one on the right had extreme emotio neglect from a mother who rejected her. The effect on physi growth in this "maternal deprivation syndrome" is obvious; for nately, this condition is rare. The emotional response probl affects physical growth by altering hormone production, but mechanism is not fully understood. (Courtesy Dr. F. Debusk.)

FOR AUTHOR USE ONLY

Hormones

Prenatal hormones:

- Chorionic somatotropine
- Fetal insulin: permissive action on growth hormone and increased affinity of fetal cells.
- Growth hormone.
- Somatomedins: actual mechanism of action of growth hormones through SM-A, SM-C and IGF I,II.
- Thyroid hormones: early extra uterine central nervous system development, normal linear growth and sexual development.
- Sex steroids
- Prolactin

Post natal growth:

- Somatotropines:alters the DNA, RNA synthesis &leading to increased production of proteins.
- Sex steroids : osseous maturation

Teratogens affecting Dentofacial development:

- Agent capable of producing embryological defect if given at critical time. Teratogens in first trimester leads to abortion mostly, in second trimester leads to organogenesis defect and in third trimester leads to the growth defect like hypoplasia.

TERATOGENS	EFFECT
Aminopterine	Anencephaly
Aspirine	Cleft lip & palate
Cigarette (hypoxia)	Cleft lip & palate
CMV	Microcephaly, Hydrocephaly, Micro-opthalmia
Dilantin	Cleft lip & palate
Ethyl alcohol	Central mid face deficiency
6-mercaptoupurine	Cleft palate
13-cis Retinoic acid	Hemi facial microsomia

FOR AUTHOR USE ONLY

Rubella virus	Micropthalmia, cataracts, deafness
Thalidomide	Hemifacial microsomia, treacher collin syndrome
Toxoplasma	Microcephaly,hydrocephaly,micropthalmia
X-radiation	Microcephaly
Valium	Cleft lip & palate
Vitamin-d excess	Premature suture closure

FOR AUTHOR USE ONLY

Neuromuscular functions

- Swallowing (congenital unconditional reflexes)
- Breathing (congenital unconditional reflexes)
- Speech (congenital unconditional reflexes)
- Conditional reflexes

Masticatory function

- Craniofacial growth is a dynamic phenomena whose structural-functional significance at any given time is transient expression of past and future as well as present condition
- Masticatory muscle - masseter

- temporalis
- medial pterygoid
- lateral pterygoid

Control Process in Facial Growth and Development or Theories of Growth Control

Introduction:

Since a major part of the need for orthodontic treatment is created by disproportionate growth of the jaws, it is necessary to determine how skeletal growth is and dentofacial deformity. However, exactly what determines the growth of jaw remains unclear and is the subject of intensive research. Through the year's no. of theories have been put forward to explain the determinant of craniofacial growth.

FOR AUTHOR USE ONLY

The various theories of growth are listed below.

- Genetic Theory
- Sutural Dominance Theory
- Cartilaginous Theory
- Functional Matrix Theory
- Von Limborg's Theory
- Counterpart Theory
- Enlows Expanding V Principle

CONCEPT OF BIOMECHANICAL EQUILIBRIUM:

- Growing muscles exceeds the capacity of the bone to support it, and osteoblasts are thereby triggered to form the new bone in response. When muscle and overall body growth is complete, the bones attain biomechanical equilibrium with the muscle.But growth control is more complex than this explanation.

Wolf's law in 1899:

- "bone grows and develops in such a manner that composite of physiologic forces exerted on it are accommodated by the bones developmental process, thereby adapting its structure to its complex of functions."
- No explanation of the forces acting on the osteogenic connective tissue that actually remodels the bone.

FOR AUTHOR USE ONLY

Genetic theory

This is one of the earliest theories put forward by Dr. Allen Brodie in 1927 and states that cranial differentiation is largely genetically determined and is preplanned. It is common that certain types of malocclusion run is families. E.g. Hapsburg jaw and prognathic mandible of the German royal family or similar malocclusion seen in parents & there children.

Malocclusion could be produced by inherited characteristics in two major possible ways.

- An inherited disproportion between the size of teeth and size of jaw producing crowding or spacing of teeth.
- Inherited disproportion between size or shape of the upper and lower jaw causing improper occlusal relationship.

The more independently there characteristics are determined, the more likely that disproportion could be inherited.

Primitive population characterized by genetic isolation and uniformity have less frequent malocclusion than the modern groups.

Urban areas have larger group people where opportunity for mating outside one's own small population usually have high prevalence of malocclusion and greater variety malocclusion problems.

This view of malocclusion as a primarily a genetic problem was strengthened by breeding experiments with animal MOST influential individual on this regard was professor STOCKARD.

He cross breed the dogs and indicated that dramatic malocclusion occurred in the dogs.

FOR AUTHOR USE ONLY

- The orthodontic speciality is faced with the evidence that genetic factor play a predominant role in the aetiology of malocclusion (Markovic, 1992) .Unusual feature of vertebrate facial development is the origin of the facial mesenchymal which arise from neural crest cells. They disrupt the Ectodermal –Mesodermal junction and migrate into the underlying tissue as ecto-mesenchymal cell. During their migration they undergo a number of interactions with the extra-cellular matrix, and with adjacent epithelia to determine the nature and patterning of the neural, skeletal and connective tissue structures they will form.

- Their migration is under the control of homeobox genes. Homeobox gene is regarded as master gene. Genes interested in craniofacial development-hox family
  - -Msx1,Msx2(muscle segment)

- -Dlx(distalless)
- -Otx(orthodontical)
- -Gsc(goosecoid)
- -Shh(sonic hedgehog)

- The proteins encoded by these genes are transcription factor.Transcription factor can switch gene on and off.Therefore control the coordinated cascade of molecular events which, in turn, control patterning and morphogenesis (Thesleff1995).

Shortcomings

- Explanation only at the molecular level and no correlation to the macroscopic morph genesis. Explanation is till protein synthesis, no idea about nature, timing, amount, actual effect of proteins and Effect of environment is overlooked.
- However the results in the STOCKARD experiment were misleading because the dogs carry genes for achondroplasia. It is a condition in which there is a deficient synthesis and growth of cartilage. It is autosomal dominant trait with partial penetrance. Simply meaning that it is expressed more dramatically in some individual than in others. Hence most malocclusion produced in the stockyard breeding experiment can be explained not on the basis of inherited jaw size but by the extent to which achondroplasia was expressed in that animal.
- The results of out breeding in human population also cast doubt on the hypothesis that independently inherited tooth and jaw characteristic are a major cause of malocclusion e.g. investigation carried out in HAWAII by CHUNG et al.

HOWAII had homogeneous population of Polynesian people with large stature broad and well developed jaws, and distinctive form of lower

FOR AUTHOR USE ONLY

jaw. ROCKER JAW. After migration of European, Chinese and Japanese group and arrival of small no. of other racial and ethnic groups it resulted in heterogeneous modern population. Tooth size Jaw size and jaw proportion were all different for the Polynesian, Oriental, European contributors to the Hawaiian melting pot. Therefore if teeth and jaw characteristic were inherited independently, high prevalence of severe malocclusion would be expected in this population.

However the prevalence and types of malocclusion in the current Hawaii population do not support this consult.

From the Bolton-bush growth study after examination of cephalometric radiographs and dental casts it was concluded that heritability of craniofacial (skeletal) characteristics was relatively high than that of dental occlusal characteristics. Skeletal characteristic heritability estimates increases with age while that of dental characteristics heritability estimates decreases indicating increases environmental contribution to dental variation.

FOR AUTHOR USE ONLY

SICHER'S HYPOTHESIS (SUTURAL DOMINANCE)

Sicher deduced from the many studies using vital dyes that the sutures were causing most of the growth; in fact, he said " …the primary event in sutural growth is the proliferation of the connective tissue between two bones. If the sutural connective tissue proliferates it creates the space for oppositional growth at the borders of the two bones". Replacement of the proliferating connective tissue was necessary for functional maintainance of the bones. He felt that the connective tissue in sutures of both the nasomaxillary complex and vault produced forces, which separated the bones, just as the synchondroses expanded the cranial base and the epiphyseal plates lengthened long bones. Sicher viewed the cartilage of the mandible somewhat differently, stating that it grew both interstitially, as epiphyseal plates, and appositionally, as bone grows under periosteum. His ideas came to be called the "sutural dominance theory," but it would seem he held sutures, cartilage, and periosteum all responsible for facial growth and assumed all were under tight intrinsic genetic control.

FOR AUTHOR USE ONLY

This theory was discredited for the following reasons

a. In an area of the suture between two facial bones is transplanted to another location , the tissue does not continue to grow. This indicates a lack of innate growth potential in the sutures.
b. If this theory were correct, growth at the sutures should occur independently of the environment and it would not be possible to change the expression of growth at the sutures very much. However it has been noted that growth at the sutures will respond to the outside

influence under a number of circumstances. If cranial or facial bones are mechanically pulled apart at the sutures, new bone fill in and the bones become larger than they would have been otherwise. If a suture is compressed, then bone growth at that site will be impeded. Thus sutures must be considered as areas that react but not the primary determinant of growth.

c. Translatory growth of the bones continue normally either in the absence of sutures or through extrepation in experimental animals.
d. In untreated clefts of palate, though suture is not present growth is taking place
e. Microcephaly and hydrocephaly gave doubts about the intrinsic genetic stimulus of the sutures.

FOR AUTHOR USE ONLY

SCOTT HYPOTHESIS (cartilaginous theory)

Another major theory is that the determinant of the craniofacial growth is growth of cartilages. The fact that cartilage does the growing while bones merely replaces it, makes this theory attractive for the growth of the bones.

Scott noting the prenatal importance of cartilaginous portions of the head, nasal capsule, mandible and cranial base felt that they continued to dominate facial growth postnatally. He specifically emphasized how, the cartilage of the nasal septum during its growth paced the growth of the maxilla Scott felt that sutural growth came in response to the growth of other structures including cartilagenous elements, brain, eyes, etc

As mentioned earlier the proponents of the cartilage theory hypothesize that the cartilagenous nasal septum serves as a pacemaker for maxillary growth. If the sutures of the maxilla served as reactive areas, like they seem to do, they would react to this translation by forming new bone when the sutures were pulled apart by the forces from the growing cartilage. Although the amount of nasal cartilage reduces as growth continues, cartilage persists in this area throughout life the pacemaker role is certainly possible.

FOR AUTHOR USE ONLY

Two kinds of experiments were carried out to test the idea that the cartilage can serve as a true growth center.

a. **Transplanting cartilage**: Transplantation experiments demonstrate that not all skeletal cartilages are the same when transplanted. If a piece of the epiphysial plate of a long bone is transplanted, it will continue to grow in new location or in culture showing that these cartilages do have update growth potential. It is difficult to obtain cartilage from the cranial base synchondroses to transplant, perhaps

this explains why cartilage from this area do not grow in vitro as well as the epiphysial cartilage. In the more precise recent experiments the nasal cartilage was found to grow nearly as well as the epiphysial cartilage in culture. In recent more precise studies the mandibular condylar cartilage showed significantly less growth than the other cartilages.

From these experiments, the other cartilages appear capable of acting as growth centers but the mandibular condyle does not.

b. **<u>Effect of removing cartilage at an early age on growth</u>**: The basic idea is that if removing a cartilagenous area stops or diminishes growth perhaps it really was an important center for growth. Extripating a young rabbit's septum caused a considerable deficity in growth of the midface. However it can be argued that the surgery itself and the accompanying interference with blood supply to the area, not the loss of cartilage, cause the growth changes. Even atraumatic removal of the cartilage of nasal septum resulted in a grossly deficient midface, leading most observers to conclude that the nasal septum does have some innate growth potential, whose loss makes a difference in maxillary growth.

FOR AUTHOR USE ONLY

Two excellent studies carried out in Scandinavia in 1960 by Gilhuus Moe and Lund demonstrated that after fracture of the mandibular condyle in a child, there was an excellent chance that condylar process would regenerate to approximately its original size and a small chance that it would overgrow after the inury. In experimental animals after a fracture, all of the original bone and cartilage resorbs, and a new condyle regenerates directly from the periosteum at the fracture site. Although there is no direct evidence that the cartilage layer itself regenerates in

children after condylar fractures, it is likely that this occurs in humans also.

However 15% to 20% of the Scandinavian children studies who suffered a condylar fracture, there was a reduction in growth after the injury. This growth reduction seems to relate to the amount of trauma to the soft tissues and the resultant scanning in the area.

It appears that the growth at the mandibular condyle is much more analogous to growth at the sutures of the maxilla, entirely reactive, than to growth at the epiphysial plate.

Lantham elaborated on Scott's ideas about the nasal septum and the maxillary growth, emphasizing the role of the septo-premaxillary ligament beginning in the later part of fetal period. He felt that the maxillary sutures began as sliding joints adopting to initiating growth forces elsewhere, but later manifest increasing osteogenesis, contributing to the main displacing force at the force surface. Thus he combines ideas of Scott, Sicher and Moss.

FOR AUTHOR USE ONLY

Scott feels that the cartilagenous parts of the skull must be recognized as primary centres of growth. The nasal septum is found to be major contributor in maxillary growth.

Histological research validates much of the Scott hypothesis. Both pressure and tension have little effect on cartilagenous growth.

Hunter and Enlow stated that the response of the cranial base to the growing brain is comparitively less than that of the bones of cranial vault. The view point that synchondroses are primary centres of growth is supported by research of Scott,, Burdi, Petrovic and others.

In cleft palate cases, the maxillary growth has been retarded by scar tissue, the nasal septum continue to grow and bends into a characteristic “S”shape. Thus according to Scott, the synchondrosis, nasal septum and condylar cartilage are the major growth centres which bring about growth of skull.

FOR AUTHOR USE ONLY

Petrovics hypothesis (servosystem theory)

Cybernetics is a term applied to the interdisciplinary study of control and communication in animals, human beings,machines and organizations. Cybernetics talk about the connections between the individual components that the complex. It does not say anything about the components themselves but the components and the communication between them. This is another means that the physiological properties of the craniofacial skeleton and other units are not due to the action between cells and their intercellular substance but due to the interaction between the whole tissue and the organs which are connected with each other and through its feedback. The important point is that no local feedbacks are so far detected. So, the study of cybernetics is nothing but identifying and analyzing these feedbacks.

FOR AUTHOR USE ONLY

On identifying the complexity of the process, Petrovic found out that only an electronic theory used to describe the communication and control mechanisms of a computer can atleast satisfactorily define the whole process of stomatognathic growth. The theory of cybernetics is mainly used in Robotics in engineering.

A physiological system designed for maintenance inspite of disturbances with a specific correspondence between the input and the output present is termed a closed loop control system.

Thus a closed loop system has a feed back loop and a comparator.

Comparator is a device which compares the feedback signal to the reference input. Thus a precision of a closed loop system depends on the comparator. The reference input is a signal established as a standard of comparison. Thus the closed loop system has a comparator and feedback loop whereas the open loop system has one.

The closed loop control system has two varieties:

1. **Regulator**:The main input is constant and the comparator detects the disturbances. The regulator is a negative feedback mechanism. i.e. any disturbance causing a change on this tends to restore the state of the disturbed system to its initial condition. In a servosystem the main input is not constant but it varies with time.
2. **The command**: It is a signal functioning independently of the feedback mechanism. It affects the behaviour of the control system without being affected by the results of the consequences of the behaviour (Eg:- Growth hormone, not being influenced by variations of the craniofacial growth).

FOR AUTHOR USE ONLY

The Cybernetic Functional Diagram:

i. Command: The command is formed by variations in the level of growth hormone, testosterone, oestrogen, cortisone, etc.
ii. Reference input elements: This is a chain of elements establishing a relationship between the command and the reference input. These are formed by example, the septal cartilage, septopremaxillary ligament and the forward growth of maxilla.
iii. The reference input: The reference input is the signal established as a standard of comparison. Eg:- Sagittal positioning of the maxilla as felt by the mandible
iv. Peripheral comparator: It is the relation between maxilla and mandible through dentition
v. Performance : performance is the occlusion and location of teeth

vi. Performance analyzing elements: These are formed by the proprioceptive fibres of the periodontal, dental reticular, muscular tissue and the brain.

vii. Central controller: In the brain there is a sensory engram or a central controller which compares the position of the mandible in relation to the maxilla. This central comparator formed as a result of the repetitive positioning of the mandible in a particular position or nothing but the neuromuscular adaptation.

If there is any deviation between what the proprioceptive fibres pickup and the central engram, deviation signal arises. The deviation signal acts on the controller of the lateral pterygoid muscle to move the mandible such that the deviation signal is reduced.

The lateral pterygoid muscle acts on the condylar cartilage and the retrodiscal pad and alters the growth of the mandible. The signal from the actuator is not enough to bring about the increased growth. Some sort of amplification occurs at this level. This growth being controlled by actuator is known as the controlled system.

FOR AUTHOR USE ONLY

What happens after this is the controlled variable or the output. This can be:

1. Change in the mandibular angle
2. Change in the condyle dental arch distance
3. forward growth of the mandible
4. forward positioning of the jaws

Now lets see what happens when a functional appliance is placed in a patient's mouth. Here an environment is created such that the mandible feels that the previous position of the maxillary has changed and it is now in a more anterior position. This is a reference input that says that the maxilla is in a forward position. The comparator finds out the error and informs the

performance analyzing system. In turn, a deviation signal is created and the controller tells the actuator to act and reduce the error. The final result is a variation in the controlled system in the form of an increased condylar growth and we get a new output, i.e. an anterior placement of mandible.

So, the changes brought about by a functional appliance not only changes the size, shape and position of the mandible but also creates a new neuromuscular environment for it to function.

Hence the result brought about by such a means must be more stable with less tendency towards relapse. As we know, one of the most important factors in determining the stability of the orthodontic treatment is the muscle balance.

Figure 2-7. Elements and organization of a servosystem.

VAN LIMBOURGH'S THEORY:

Limbourgh poses three main questions concerning the control of morphogenesis of the skull

1. Are there, in the embryonic phase, any causal relationship between the development of the skull on one hand, and the presence of the primordia of the other head structures on the other?
2. How is co-ordination between the endochondral and intramembranous bone growth brought about within the skull once it is formed?
3. In which way is co-ordination between the skull growth and that of the other structures realized?

To answer these questions, analysis must be made of the more obvious controlling and modifying factors.

1. Intrinsic genetic factors
2. Epigenetic factors
3. Local and general environmental factors

FOR AUTHOR USE ONLY

According to Van Limbourg, the three popular theories of growth i.e. The Functional Matrix Theory by Moss, Sutural Theory by Sicher and The Genetic Theory were not satisfactory, yet each theory contains elements of significance that cannot be denied. He hence put forward a multifactorial theory that combines the views of all three theories.

Van Limbourg has suggested the following five factors that he believed controls growth:

Intrinsic genetic factors: they are the genetic control of the skeletal units themselves.

Local epigenetic factors: bone growth is determined by genetic control originating from adjacent structures like brain, eyes etc.,

General epigenetic factors: they are genetic factors determining growth from distant structures. E.g, Sex hormones, growth hormone etc.,

Local environmental factors: they are non-genetic factors from local external environment. E.g, habits, muscle force, etc.,

General environmental factors: they are general non-genetic influence such as nutrition, oxygen etc.,

The views expressed by van Limborgh can be summarized in the following six points:

1. Chondrocranial growth is controlled mainly by the intrinsic genetic factors.
2. desmocranial growth is controlled by any few intrinsic genetic factors.
3. The cartilaginous parts of the skull must be considered as growth centers.
4. Sutural growth is controlled mainly by influences originating from the skull cartilages and from other adjacent skull structures
5. Periosteal growth largely depends upon growth of adjacent structures
6. Sutural and periosteal growth are additionally governed by local non-genetic environmental influence.

ENLOW AND BANG'S "V" SHAPED PRINCIPLE

Enlow and Bang applied the principle of area relocation to the multidirectional growth movement of the craniofacial bone.

As the dynamic process continues, specific local areas come to occupy actual positions in succession (or) as the entire bone enlarges. This growth shifts and changes involve corresponding and sequential remodeling adjustments in order to maintain the same shape, relative positions and constant proportions of each individual area.

A most useful and basic concept in facial growth is the "V" principle.

Many facial and cranial bones have a "V" shaped configuration.

Bone deposition occurs on the inner side of the "V" and resorption takes place on the outer surface of the "V" deposition also take place at the ends of the 2 arms of "V".

FOR AUTHOR USE ONLY

The direction of movement is towards the wide end of the "V". Thus simultaneous growth movement and enlargement occur.

Eg: Base of a mandible, ends of long bones, mandibular body, palate etc

ENLOWS COUNTERPART PRINCIPLE OF CRANIOFACIAL GROWTH

This principles states that "the growth of any given facial or cranial part relates specifically to other structural and geometric counterparts in the face and cranium".

FACIAL GROWTH PROCESS

Multiple growth process parts of face and cranium is described as individual regions. These regional growth process take place simultaneously, even though they are presented here as a sequence of separate stages. Growth increases are shown in such a way that same craniofacial form and pattern are maintained, which is known as Balanced Growth in which form and proportions Remain Constant.

FOR AUTHOR USE ONLY

However a perfectly balanced mode of growth never occurs in real life in all parts of face and cranium. The growth in real life is Imbalanced. Facial growth description are presented as a Balanced series because of Two Reasons:

a. To understand concept of growth balance.
b. To recognize and explain facial imbalance i.e. where and how much disproportion had taken place.

No face has yet been encountered that has perfect Anatomic and Geometric "Balance". Growth process outlined here follows the counterpart of principle of craniofacial growth.

The different parts and counter parts are :

a. Nasomaxillary complex relates to the anterior cranial fossa

b. Horizontal dimension of the pharyngeal space relates to the middle cranial fossa

c. Middle cranial fossa and breadth of ramus are counterparts

d. Maxillary and mandibular arches are mutual counter parts

e. Bony maxilla and corpus of mandible are mutual counterparts

f. Maxillary tuberosity and lingual tuberosity are counterparts

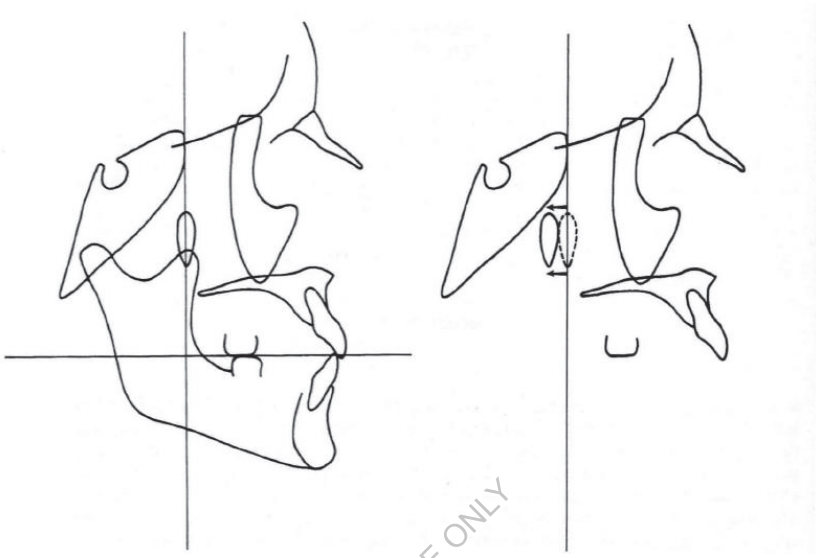
Growth process of each region is presented as two separate parts:

a. Remodelling
b. Displacement

FOR AUTHOR USE ONLY

REGIONAL CHANGE1 : REMODELLING

There is bone deposition in the maxillary tuberosity region .this lengthens the maxillary arch in a posterior direction. This is shown by posterior movement of ptm.



FOR AUTHOR USE ONLY

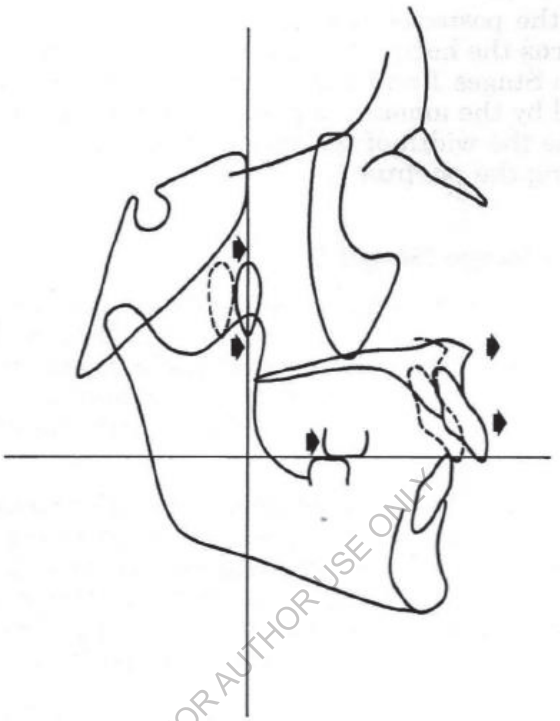
REGIONAL CHANGES 2:DISPLACEMENT

Primary displacement of maxilla in anterior direction by same amount as the growth in posterior region(tuberosity) takes place

As the bone is displaced ,it undergoes remodeling in order to keep pace with the amount of displacement.

REGIONAL CHANGE 3:

Body of the mandible relates specifically to the bony maxillary arch. Body of the mandible lengthens to match the growth of the maxilla by remodeling of the ramus by an amount equal to the growth of maxilla. However the maxilla is still prognathic and in a class.



FOR AUTHOR USE ONLY

REGIONAL CHANGE 4:

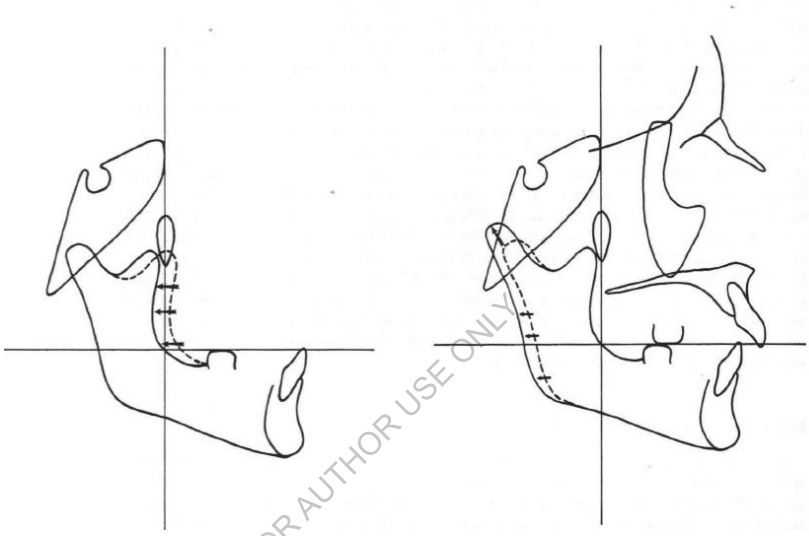
Condyle and posterior part of ramus grow posteriorly. Due to growth of posterior part of ramus, the original width of ramus is restored i.e. the amount of anterior ramus resorption is equalized by posterior ramus deposition.

REGIONAL CHANGE 5:

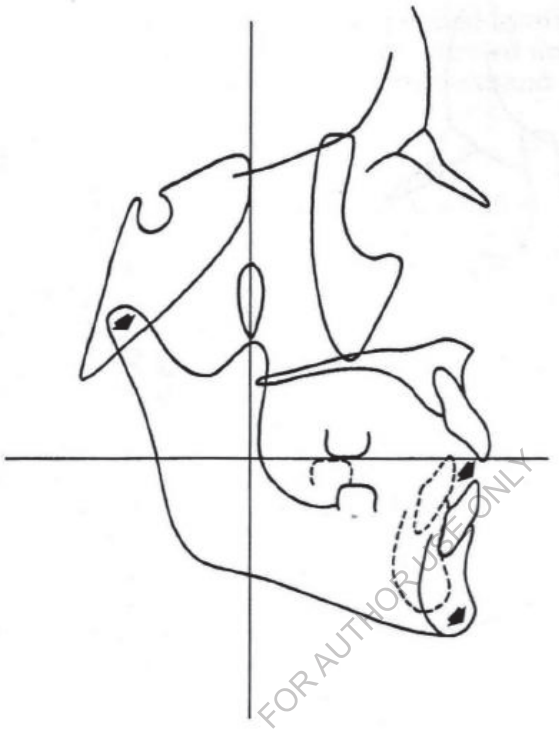
The whole mandible is displaced anteriorly by the same amount the ramus has relocated posteriorly due to primary displacement.

This places the mandibular arch in proper position relative to the maxillary arch just about it i.e. Class I Relation of teeth has returned.

However the occlusion is separated because the mandible is displaced inferiorly as well as anteriorly.



FOR AUTHOR USE ONLY

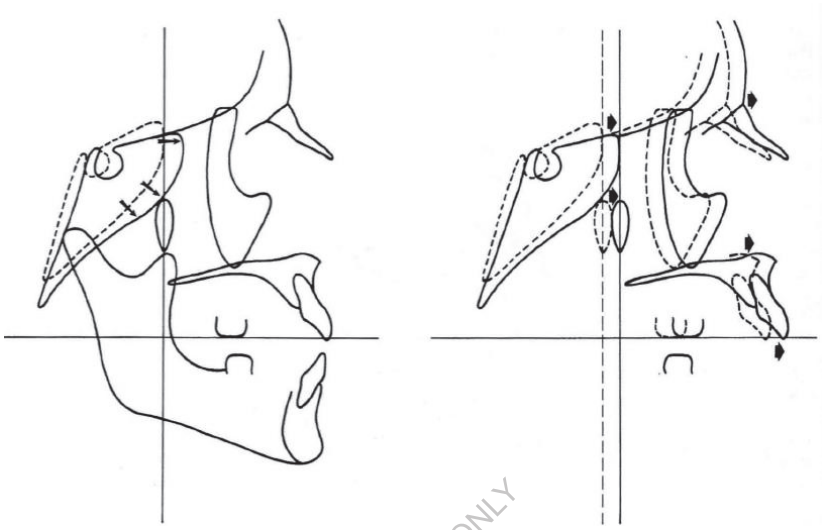


FOR AUTHOR USE ONLY

REGIONAL CHANGE 6:

When all the above-mentioned process is taking place, the dimensions of the middle cranial fossa have also been increasing. Increase in size is brought about the resorption on the endocranial side and deposition on the ectocranial side of cranial floor.

This projects it anteriorly beyond the vertical reference line.



FOR AUTHOR USE ONLY

REGIONAL CHANGE 7:

All cranial and facial parts lying anterior to the middle cranial fossa become displaced anteriorly as a result.

The whole vertical reference line moves anteriorly to the same extent that the middle cranial fossa expands in a forward direction. This is a secondary type of displacement.

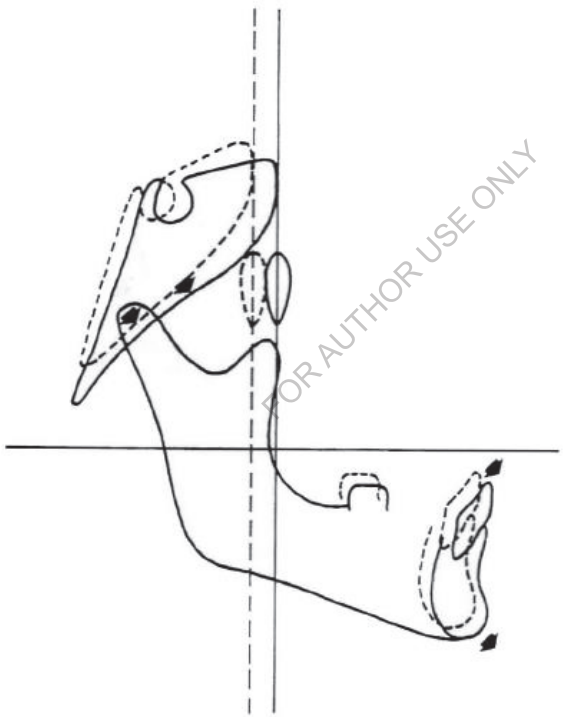
REGIONAL CHANGE 8:

Expansion of the middle cranial fossa displaces the mandible downward and forward but to a lesser extent than it displaces the maxilla. The result is an offset horizontal placement between the upper and lower arches. In this stage, the molars are in class II relation and the overjet is increased.

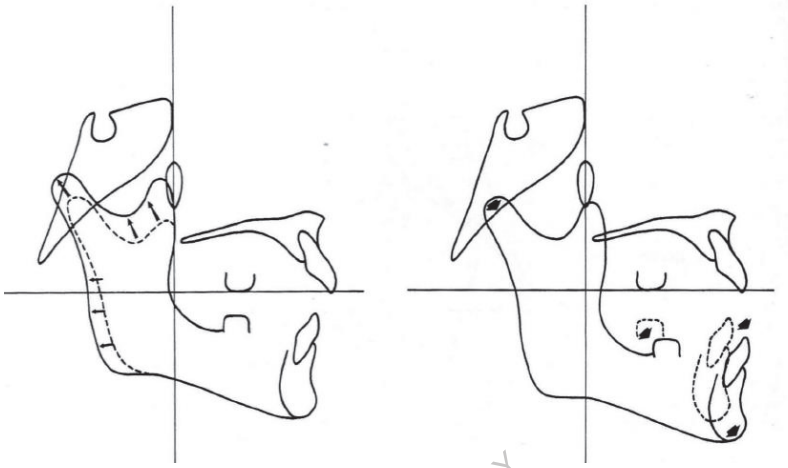
REGIONAL CHANGE 9:

Just as the lengthening of the middle cranial fossa places the maxillary arch in a more anterior position, the horizontal growth of the ramus places the mandibular arch in a like position.

The horizontal extent of middle cranial fossa elongation is matched by the corresponding extent of horizontal increase by the ramus.



FOR AUTHOR USE ONLY



FOR AUTHOR USE ONLY

REGIONAL CHANGE 10:

The entire mandible is displaced anteriorly at the same time that it grows posteriorly.

The amount of this anterior displacement equals:

a. The extent of posterior ramus and condylar growth
b. Amount of middle cranial fossa enlargement anterior to the condyle.
c. The extent of anterior movement of the vertical reference line
d. The extent of resultant anterior maxillary displacement.

The oblique manner of the condylar growth produces an upward and backward projection of the condyle with a corresponding downward and forward displacement of the mandible. The ramus thus becomes vertically and horizontally enlarged. This results in a further descent of the mandibular arch and separation of occlusion.

The total extent of this vertical growth must match the total vertical lengthening of the nasomaxillary complex and upward eruption and drift of the mandibular dentoalveolar arch if the same facial balance is to be achieved.

Now the protrusion of maxilla is matched by a corresponding protrusion of mandible. Now the molar relation is class I and the overjet has returned to normal.

REGIONAL CHANGE 11:

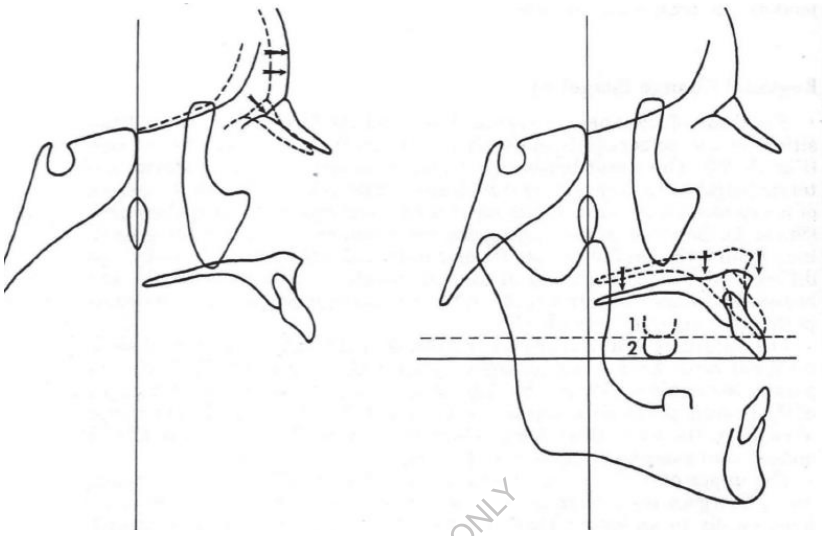
The floor of anterior cranial fossa and the forehead grow by deposition on ectocranial side with resorption from endocranial side. The nasal bones are displaced anteriorly. The postero –anterior length of the anterior cranial base is now in balance with its counterpart, the maxillary arch.

FOR AUTHOR USE ONLY

REGIONAL CHANGE 12:

The vertical lengthening of the nasomaxillary complex is brought about by a composite of:

a. Growth by remodeling i.e. resorption on the nasal side of the palate and deposition on the oral side, there by relocating it inferiorly and providing for the vertical enlargement of the overlying nasal region.
b. A primary displacement movement associated by its own enlargement.



FOR AUTHOR USE ONLY

REGIONAL CHANGE 13:

Vertical growth by displacement is associated with growth at various sutures of the maxilla. The increment of bone growth in the sutures exactly equals the amount of inferior displacement of the maxilla.

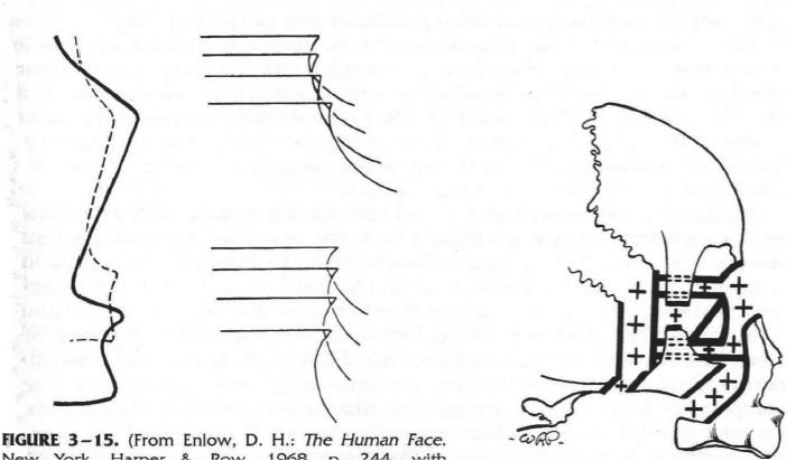


FIGURE 3–15. (From Enlow, D. H.: *The Human Face.*
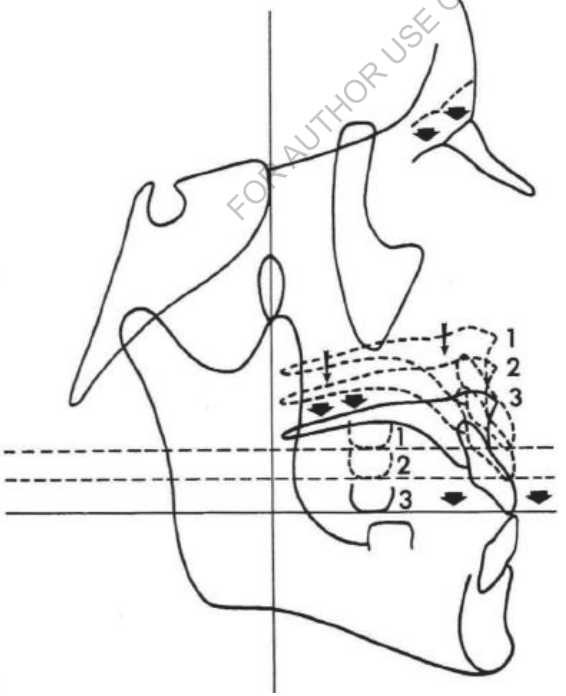
New York, Harper & Row, 1968, p. 244, with

FOR AUTHOR USE ONLY



REGIONAL CHANGE 14:

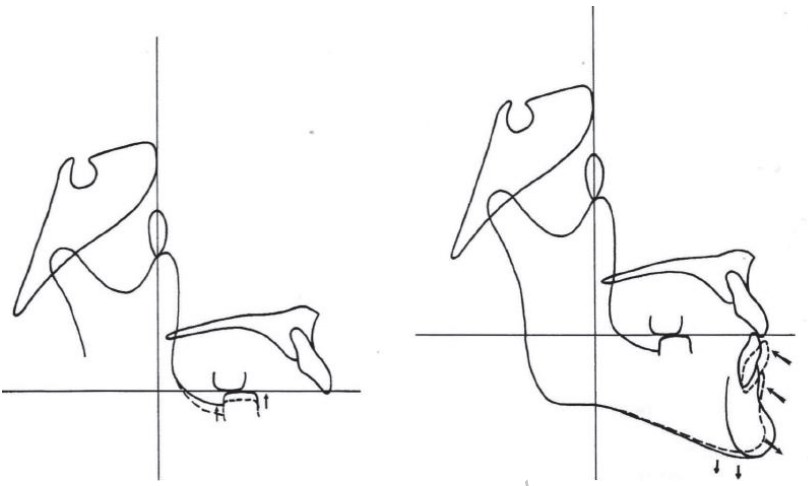
The amount of vertical separation between the upper and lower arches caused by the vertical growth of the middle cranial fossa and ramus must be balanced by an equivalent amount of vertical growth in the nasomaxillary complex and the dentoalveolar region of the mandible. As the nasomaxillary complex moves downwards, the mandibular teeth (drift) and alveolar bone grow upward to attain full occlusion.

REGIONAL CHANGE 15:

While stage 14 is going on, there are remodeling changes in the incisor alveolar region, the chin and the corpus of mandible.

The lower incisors undergo lingual tipping so that there is proper overbite. This involves posterior rotation movement of lower incisors as they drift superiorly: Resorption on outside surface of alveolar region above the chin occurs, the alveolar bone moves backwards as the incisors undergo lingual drift. Bone is added on the external surface of the chin and on the corpus of the mandible.

FOR AUTHOR USE ONLY



FOR AUTHOR USE ONLY

REGIONAL CHANGE 16: Remodeling

Remodelling takes place in the zygoma and malar region. The malar region grows posteriorly by bone deposition on its posterior side and resorption on the anterior side. However since the deposition is more than the resorption, the whole malar protruberance becomes larger. The zygomatic process grows posteriorly by anterior resorption and posterior deposition (similar to coronoid process).

Zygomatic arch also enlarges considerably by bone deposition along its inferior edge. The arch increases in width, latterly by deposition on the lateral surface and resorption on the medial surface.

REGIONAL CHANGE 17: Displacement

As the whole maxillary complex is displaced anteriorly and inferiorly and as it simultaneously increases in size, the zygoma is moved anteriorly and inferiorly by primary displacement as it enlarges. The zygoma thereby

proportionately matches the maxilla in the direction and amount of horizontal and vertical growth and in the direction and amount of primary displacement.

FUNCTIONAL MATRIX HYPOTHESIS

Functional matrix hypothesis was put forward by Melvin Moss in early 60s. He worked on the cocept put by Van Der Klauvw – The Functional Cranial Component.

In the year 1960 first paper was published in the American Journal of Physical Anthroplolgy by Moss and Young. In the year 1981, Moss in his classical statement defined his Hypothesis, as:

"The origin, growth and maintenance of all skeletal tissues and organs are always secondary, compensatory and obligatory to temporally and operational prior events or processes that occur in specifically related Non-skeletal tissues, organs or functional spaces".

According to Moss certain functions are carried out in craniofacial complex like:

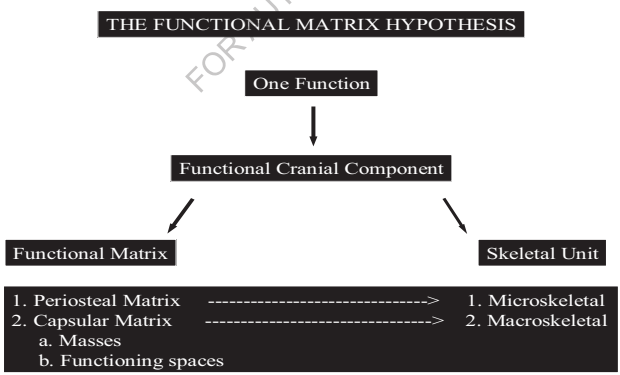
1. Digestion

2. Respiration
3. Vision
4. Olfaction
5. Audition
6. Equilibrium
7. Speech
8. Neural Integration

Each function is carried out by a Functional Cranial Component. Each functional cranial component is composed of 2 parts:

1) A functional matrix, which actually perform the function, usually a soft tissue.
2) A skeletal unit, which biomechanically supports and protects its specific functional matrix.

FOR AUTHOR USE ONLY



SKELETAL UNITS

Skeletal units are composed of variety of osseous, cartilaginous tendinous tissues. They are not the equivalents of the "bones" of formal classic osteology. As such, there is no biological reality in terms maxilla and mandible.

Skeletal units can be divided into:

a. Microskeletal units
b. Macroskeletal units

Macroskeletal units: When adjoining portions of a number of neighbouring "bones" are united to function as a single cranial component termed as Macro skeletal units.

E.g.

(I) The entire endocranial surface of the calvaria is one such Macroskeletal unit, serving to protect and support the enclosed neural mass

(II) The orbital surfaces of all the bones comprising the bony orbit, form another such macro unit subserving the functional demands of the orbital mass.

FOR AUTHOR USE ONLY

Micro skeletal units: When a bone that makes up skeletal units consists of a number of skeletal units – these units are called Micro skeletal units.

The various Micro skeletal units in the mandible and the structures that are related to them are:

Coronoid process – temporalis muscle

Angular – Masseter and medial Pterygoid

Alveolar unit – Presence and position of teeth

Basal unit – Inferior alveolar neurovascular traid

Similarly, Maxilla include – Nasal

Orbital

Pneumatic

Palatal (both oral and nasal)

Some Micro skeletal units serve the same functional matrix but are separated in space. An example is the lateral surface of the mandibular angular process and a portion of the zygomatic arch, both of which are related to the functional demands of the masseter muscle.

The basic postulate is that the size, shape, position of each skeletal unit is a response to the demands for protection and or support of its specifically related functional matrix..

FOR AUTHOR USE ONLY

FUNCTIONAL MATRICES

It is a basic postulate of the method of functional cranial analysis that with the exception of embryonic tissue differentiation all other aspects of cranial skeletal tissue growth (osseous, cartilaginous and fibrous) are secondary and compensatory reflections of the morphogenetically and temporarily prior growth and operation of cranial functional matrices.

Thus the primary growth of all these matrices, taken together with the secondary growth of all of the skeletal units, comprises the totality of head growth.

Two distinct types of functional matrices

1) Periosteal matrices and
2) Capsular matrices

Periosteal matrices – acts directly and actively on microskeletal units by the process of osseous deposition / resorption or by endochondral growth

process. They produce only change in size and shape of their specific microskeletal units. These growth processes are called transformations.

Such transformations are brought about by the inter related processes of deposition and resorption of bone

E.g. of such matrices are masseter, temporalis and pterygoid muscles.

Periosteal functional matrices are vertically self-defining. They are best exemplified by the effect of muscles upon the skeletal units i.e. blood vessels, nerves and glands also produce morphologic changes in their related skeletal units. The action of temporalis muscle and coronoid process upon their skeletal units (Moss and Salentijn; 1969).

Experimental removal of mammalian temporalis muscle, or its denervation results in actual diminution of size and shape of coronoid process. Similarly it is very well established that functional hyperactivity of the temporalis produce increased coronoid process size and alteration of its shape. It is also established that the experimental or clinical alteration of muscles attaching to the other mandibular ramal skeletal units can produce compensatory changes in the temporalis muscle function.

FOR AUTHOR USE ONLY

Thus the total growth changes in all aspects of coronoid process form (size and shape) are at all times secondary and compensatory responses to the morphogenetically and temporally prior demands of the temporalis muscle function.

The complementary and interrelated process of osseous deposition and resorption bring about all responses of the osseous portions of skeletal units to periosteal matrices. The resultant effect of all such skeletal unit responses to periosteal matrices is to alter their size and / or their shape.

Such transformations are brought about by the inter related processes of deposition and resorption of bone.

Eg of such matrices are – masseter, temporalis and pterygoid muscles.

CAPSULAR MATRICES

It acts indirectly and passively on their related skeletal units, producing a secondary, compensatory "Translation" in space. These alterations in spatial position of skeletal units are brought about by the expansion of the facial capsule. Within which the facial bones arise, grow and are maintained. The facial skeletal units are passively and obligatorily moved in space as their enveloping capsule is expanded.

The oral, nasal and pharyngeal cavities, considered as functioning spaces are examples of such matrices. The enclosed capsular matrices act indirectly on macro skeletal units or on entire functional cranial component, which happen to be embedded completely within a specific capsule.

FOR AUTHOR USE ONLY

Neurocranial

Orbital

Orofacial

Otic

They do not act by the process of osseous deposition or resorption or by affecting cartilage directly. They do not alter the size or shape of the skeletal units.

But they do change their location in space. Such growth processes are termed translations. Each of these capsules is an envelope that contains series of functional cranial components (skeletal units and their related functional matrices) that are sandwiched between two covering layers).

In case neurocranial capsule – skin of dura matter are the covering layers, in orofacial capsule, the skin to mucous membranes forms it.

All intervening spaces in functional component themselves as well those between them and the limits of the capsule are filled with indifferent loose connective tissue.

Each capsule surrounds and protects a capsular functional matrix. This exist as volumes

Eg: In neurocranial capsule – brain and leptomeninges and C.S.F

In orofacial capsule – oropharyngeal functioning spaces

Otic capsule – eyeball

The calvarial bones which lying within the neurocranial capsule has contiguous micro skeletal units – the outer table

- Inner table
- Diploic space
- Sinuses

FOR AUTHOR USE ONLY

Expansion of neurocranial capsule occurs in response to the morphogenetically primary expansion of the enclosed neural mass. As this capsule expands, the enclosed and embedded calvarial skeletal tissues are passively translated in space in response to the capsular matrix.

At the same time, these same skeletal units respond to the altered demands of their periosteal matrices. They do so by expanding in area and in thickness, by altering the trabecular pattern of bone into inner and outer tables of compact bone with an intervening diploic area.

OROFACIAL MATRIX

All functional cranial components of the facial skull arise grow and are maintained in the orofacial capsule (splanchnocranial). The capsule surrounds and protects the oropharyngeal functioning spaces. It is the

volumetric growth of the functioning spaces, which is the primary morphologic event in facial skull growth.

The functioning reality of the respiratory and digestive system is their patency; and the volume of that patency is related to the general metabolic demands of the body as a whole.

The oral and pharyngeal regions have a primary function in maintaining patent airway. This is accomplished by a dynamic musculoskeletal postural balance, which is termed the "airway maintenance mechanism". The related functional cranial components are so dynamically balanced that this airway is maintained through out the range of motion of head and neck.

Growth of the enveloping capsule is produced by mitosis of its epithelial and mesenchymal cellular elements and the consequent increase in intercellular materials, which results in an expansion of the capsule as a whole. Within the capsule are the situated a number of mandibular functional cranial components, periosteal matrices together with their respective skeletal units. Because the mandibular cranial components arise and exist completely embedded within this capsule, they all necessarily are passively and secondary translated into a new position as the capsule expands. Such passive translation affects both the periosteal matrices and their skeletal units. Accordingly simultaneous with the passive translation, the individual periosteal matrices also alter their functional demands (muscle growth) these changes cause change in size to shape of their several skeletal units.

FOR AUTHOR USE ONLY

Both this neural and orofacial function originate by the process of enclosure. The orofacial capsular matrix being in those embryonic stages during which the several facial processes (medial, lateral nasal, mandibular

and maxillary arise). The probably genetically controlled interstitial growth of their underlying mesoderm (ectomesenchyme) causes the several enlargements, swellings and movements. Therefore it is growth of primordial capsule that actually form the oronasal functioning spaces.

The substantial differences between the two types of functional matrices has been emphasized also by Frankel who referred capsular matrix as

"Developmental – Mechanical" influence on facial growth and periosteal matrices. "Functional – Mechanical" influences in facial growth.

FOR AUTHOR USE ONLY

FUNCTIONAL MATRIX CONCEPT (REVISITED)

The initial version of the functional matrix hypothesis (FMH), claiming epigenetic control of morphogenesis, was based on macroscopic (gross) experimental, comparative, and clinical data. Recently revised, it now extends hierarchically from gross to microscopic (cellular and molecular) levels and identifies some epigenetic mechanisms capable of regulating genomic expression. This warranted revisiting our earlier analysis of the perennial genomic/epigenetic controversy.

The epigenetic position of the FMH may seem quixotic when molecular genetics is the premier ontogenetic research paradigm. Indeed, most clinicians and experimentalists—there are exceptions—subscribe to the two epigraphs above, stated more succinctly as "genes make us, body and mind."

Nevertheless, a continuing countercurrent of dissent claims morphogenesis is regulated (controlled, directed) by epigenetic mechanisms and processes. In addition, several new disciplines explicitly invoke epigenesis.

The epigenetic/genomic problem is a dichotomy, and dialectics is one analytical method for its resolution. The method consists of the presentation of two opposing views, a thesis and an antithesis, and of a resolving synthesis. Such a dialectic analysis is presented here in two interrelated articles that respectively consider

(1) The genomic thesis

(2) An epigenetic antithesis and a resolving synthesis. Because a comprehensive review of this problem would be encyclopedic, only selected relevant aspects of ontogeny (morphogenesis) and phylogeny (evolution) are considered here.

FOR AUTHOR USE ONLY

An Odontogenic Example of the Genomic/Epigenetic Dichotomy

Odontogenesis provides a comprehensible example. The widespread diagnostic use of vertebrate dental coronal morphology in zoological systematics, vertebrate paleontology, physical anthropology, and forensic odontology suggests to many a rigid genomic control of odontogenesis, as reflected in the temporally sequential, and spatially restricted, expression of the genomically regulated production of specific molecules as exhibited, for example, in murine molar development.

Nevertheless, data exist strongly supportive of epigenetic regulation of odontogenesis. For example, Chiclid fish are polyphyodont (have continuously replacing dental sets) and can exhibit pronounced dental phenotypic plasticity. When the fish are fed on hard-shelled mollusks, the replacing teeth are large and molariform, but when soft food is fed, those

teeth are gracile, conical, and nonmolariform. Experimentally in aquaria, the two phenotypic states may be repeatedly and arbitrarily alternated in succeeding dental generations by alternately changing the diet's consistency. Because each dental replacement cycle involves identical odontogenic stages, it is postulated that

(1) Mechanical forces, related to differential diet "hardness," generate epigenetic signals, mechanotransductively processed by dental papilla cells;

(2) These signals control at least the temporal and spatial expression of genomic products related to the development of differential tooth form, such as size and shape.

If the epigenetic/genomic dichotomy of odontogenetic regulation is unresolved, how much more so the complex topic of cephalic morphogenesis where, parenthetically, mechanical loadings also play a significant regulatory role.

FOR AUTHOR USE ONLY

The Genomic Thesis

The genomic thesis holds that the genome, from the moment of fertilization, contains all the information necessary to regulate (cause, control, direct)

(1) The intranuclear formation and transcription of mRNA

(2) Importantly, without the later addition of any other information, to regulate also all of the intracellular and intercellular processes of subsequent, and structurally more complex, cell, tissue, organ, and organismal morphogenesis: succinctly, "all (phenotype) features are ultimately determined by the DNA sequence of the genome."

In this thesis, morphogenesis is but the predetermined reading-out of an intrinsic and inherited genomic organismal blueprint where, in addition to molecular synthesis, the genome also regulates the geometric attributes of

cell, tissue, organ, and organismal size, shape, and location. For example, "specific patterns of gene regulation (cause, control, regulate, determine) the mechanisms by which a fertilized egg divides and progresses through the various decision points to yield groups of cells that are first determined to become and then actually differentiate to become specialized tissues of the right dimension and in the proper location."

The genomic thesis originated with classical (chromosomal) Mendelian genetics.Combined with the empirical data of animal breeders, it earlier provided a theoretical basis for certain human eugenic theories proposing reproductive inhibition for individuals with "undesirable and genetically (chromosomally) regulated" medical and social conditions: a policy that eventually reached historical genocidal depths.

Later, the blending of the classical chromosomal and vertebrate paleontological disciplines created the neo-Darwinian synthesis, a currently accepted paradigm of phylogenetic regulation.

Recently, molecular (gene) genetics extended the claims of the thesis to the regulation of all aspects of ontogeny (i.e., of "growth and development"). The mega-human genome project, called "the ultimate triumph of genetics, explicitly intends to:

(1) Describe the complete human genome;

(2) Demonstrate genomic controls of all developmental processes, at all structural levels, from the sub cellular to the organismal; and,

(3) In a societal context, possibly lead to some type of neoeugenics.

Many human activities now are claimed to be genomically regulated: e.g., psychological behavior; personality; alcohol and drug abuse; chronobiological cyclic behavior smoking, obesity, alcoholism, drug abuse, food-binging—indeed any attention-deficiency disorder, among many

FOR AUTHOR USE ONLY

others. The further suggestion of genomic control of intelligence generates prodigious, biomedical controversy in the social sciences and politics. And note the frequent popular press reports of the "discovery" of yet another "gene" that "controls" yet another developmental, physiological, psychological, or sociological event, process, or state.

The Biologic Bases for the Genomic Thesis

While comprehensively considered elsewhere, a brief review is useful. The somatic cells of an individual metazoan inherit two classes of molecular information:

(1) An identical diploid DNA

(2) The maternal cytoplasmic constituents of the egg: e.g., mitochondria, cytoskeleton, membranes. Only approximately 10% of the genome seems related to phenotypic ontogenesis, whereas the human genome has approximately 100,000 genes, "well over 90% does not encode precursors to mRNAs or any other RNA." With regard to individual phenotypic structural attributes, while all somatic cells commonly share approximately 5000 different polypeptide chains, each specific cell type is characterized only by approximately 100 specific proteins. And it is claimed that "these quantitative (protein) differences are related to differences in cell size, shape and internal architecture."

FOR AUTHOR USE ONLY

The encoding 10% of the DNA exists in two families; the vastly preponderant "housekeeping" genes and the nonabundant "structural" genes. The former regulate the normal molecular synthesis of agents involved in

(1) The common energetic (metabolic, respiratory) activities of all cells

(2) The specific activities of special cell types (e.g., neurons, osteoblasts, ameloblasts etc.).

These genes also regulate the synthesis of the specific molecular gene products, whose presence, absence, or abnormal molecular configuration are associated with the (human) pathologic conditions said to have a unitary genetic cause—the so-called Mendelian disorders and the single-gene disorders with nonclassic inheritance," such as Marfan syndrome, achondroplasia, osteogenesis imperfecta, and Duchenne muscular dystrophy, among many others. For some, such "disorders provide the model on which the program of medical genetics is built." In such conditions the absence of a normal type or the presence of a structurally abnormal type, of a specific biochemical or molecular structural entity is sufficient to initiate the cascade of subsequent abnormal developmental pathways, eventuating in a specific pathological state.

A physical analogy is the construction of a building wall where either the proportions of the concrete are incorrect or an insufficient number of metal reinforcing rods are used. In both cases, eventual structural collapse is possible. Substitution of intercellular proteoglycans, and of collagen fibrils, provides a corresponding skeletal tissue analogy. Here, alterations in the genomically regulated processes of molecular synthesis can produce an eventual "structural collapse" at the hierarchically higher level of a macroscopic bone. Anticipating an antithesis, note here that the claim of genomic control of the molecular syntheses underlying the formation of such elemental (molecular) skeletal tissue "building blocks" does not substantiate the further claim that the genome regulates the growth and development (the size, shape, location and histological composition) of the gross anatomical bone.

The Genomic Thesis in Orofacial Biology

FOR AUTHOR USE ONLY

There is extensive support for the genomic thesis in the orofacial biology literature, with most genetic studies of cephalic or cranial morphogenesis explicitly or implicitly assuming genomic regulation of each anatomical structure.

A characteristic article claims that prenatal craniofacial development is controlled by two interrelated, temporally sequential, processes:

(1) Initial regulatory (homeobox) gene activity and

(2) Subsequent activity of two regulatory molecular groups: growth factor families and steroid/thyroid/retinoic acid super-family. For example, "homeobox genes coordinate the development of complex craniofacial structures" and in "both normal and abnormal development, much of the regulation of the development of virtually all of the skeletal and connective tissue of the face is dependent on a cascade of overlapping activity of homeobox genes."

FOR AUTHOR USE ONLY

It is claimed that regulatory molecules can

(1) "Alter the manner in which homeobox genes coordinate cell migration and subsequent cell interactions that regulate growth"

(2) Be involved in the "genetic variations causing, or contributing to, the abnormal development of relatively common craniofacial malformations . . . perhaps modifying Hox gene activity."

Specific orthodontic implications of the genomic thesis include claims that "poorly coordination-ordinate control of form and size of structures, or groups of structures (e.g., teeth and jaws) by regulator genes should do much to explain the very frequent mismatches found in malocclusions and other dentofacial deformities." And "single regulatory (homeobox) genes can control the development of complex structures indicating that single genes can determine the morphology of at least some complex structures,"

including "how characteristic noses or jaws are inherited from generation to generation."

FOR AUTHOR USE ONLY

Critical Definitions

Clarification of this dichotomy is assisted by defining the present use of four terms: epigenetics, hierarchy, emergence, and causation.

Epigenetics: Several millennia ago epigenesis described the process(es) by which increasing structural complexity gradually arose from an originally unstructured mass, for example the stages of in vivo chick development or the gradual appearance of a pattern during weaving on a loom. Over time, many alternate, often differing, definitions appeared. Earlier, they were macroscopic in scale and considered only the extrinsic, extraorganismal environment, such as food, light, temperature, and radiations. Nineteenth century physiology added the intrinsic, intraorganismal milieu interieur, such as hormones, blood gases, nutrients, and ions.

Epigenetics, as defined here, includes

(1) All of the extrinsic (extraorganismal) factors impinging on vital structures, including importantly mechanical loadings and electroelectric states

(2) All of the intrinsic (intraorganismal) biophysical, biomechanical, biochemical, and bioelectric micro environmental events occurring on, in, and between individual cells, extra cellular materials, and cells and extra cellular substances.

Hierarchy: Biological structures are hierarchically organized, with structural and functional complexity increasing "upward" from the ever-expanding family of subatomic particles to protons, electrons, atoms, molecules, sub cellular organelles, and on to cells, tissues, organs, and organisms. While a genomic thesis claims that each higher level is achieved by the predetermined activity of the genomic information, an epigenetic antithesis suggests that hierarchical complexity results from the functioning of epigenetic processes and mechanisms, as described in the disciplines of developmental mechanics, self-organization, complexity, and chaos, among others,—topics considered further in the following epigenetic antithesis.

FOR AUTHOR USE ONLY

Emergence: This phenomenon occurs in all natural hierarchies. It consists of the appearance, at each successively higher and structurally and/or operationally more complex level, of new attributes or properties, not present in the lower levels, whose existence or functions could not in any way be predicted, even from a complete knowledge of all of the attributes and properties of any or all of the preceding lower organizational levels.

For example, full knowledge of all the attributes and properties of an osteocyte does not permit prediction of the attributes and properties of any

type of bone tissue. And full knowledge of all attributes and properties of all constituent bone tissue types does not permit prediction of the form (size and shape), growth, or functions of a macroscopic "bone."

Emergence is not genomically controlled. Instead, the integrated activities of all the attributes in a given hierarchical level self-organize to produce the next higher level of complexity. In every real sense, biologic structures "build" themselves; that is, bones do not grow, they are grown. Epigenetic processes and mechanisms are regulatory (causal) of hierarchical organization and of emergence and self-organization.

Causation: From this vast topic, we consider only how the attributes of a given biologic structural level "cause" (control, regulate, determine) the attributes of the next higher level. For example, what causes osteogenesis on the ectofacial surface the left mandibular angular process of a given 14-year-old male? The genomic thesis holds that this process was predetermined; i.e., that individual's osteoblastic genome contained, at the moment of fertilization, all the information necessary to regulate where, when, for how long, in what direction, in what amount, and at what rates, bone formation and remodeling will occur in that individual, given the absence of disease and the presence of the usual and necessary extrinsic (environmental) factors, such as adequate nutrition, and the customary normal physiological states, such as are presumed to exist in physiology's hypothetical normal human.

FOR AUTHOR USE ONLY

The antithesis (and the FMH) suggests that epigenetic stimuli, created by operations of related functional matrices and their skeletal unit adaptive responses, create the "new" information sequentially, as mandibular ontogenesis proceeds. All ontogenesis exhibits developmental "cascades,"

with multiple branching points where decisions are made between alternate developmental pathways. Such decisions are not predetermined by encoded genetic information, but instead are responses to some epigenetic stimulus (i). Hierarchy, emergence, and causation are topics of the greatest significance in any critique of the genomic hypothesis, because the scope and content of molecular genetics is precisely that; it deals with only the molecular level of structural organization. The genomic hypothesis proposes no pathways from molecules to morphogenesis. Customarily, in craniofacial literature, the existence of two "facts" is stated:

(1) That at the molecular level, a particular gene (or group of genes) exists

(2) That at some higher, macroscopic level, some clinical state of normal growth and development or of malformation and/or malfunction is observed.

Without positing any specific mechanisms or processes at each intervening hierarchical level of the developmental cascade, it is simply stated that fact 1 is the cause of fact 2. For example, "it is demonstrated that synpolydactyly, an inherited human abnormality of the hands and feet, is caused [italics mine] by expansions of a polyalanine stretch in the amino-terminal region of HOXD13."

FOR AUTHOR USE ONLY

In the genomic thesis morphogenesis is reduced to molecular synthesis.

The Classification of Causation: There are four principal causes of ontogenesis: material (with what?), formal (by what rules?), efficient (how?), and final (why?). These may be categorized as either intrinsic (material and formal) and extrinsic (efficient); final cause (teleology) is not considered further. Of importance, both material and formal causes are classified as prior causes, i.e., existing before the creation of some specific

state or structure. Efficient cause is proximate; i.e., its operation immediately causes the creation of a new state or attribute. Material and formal causes are intrinsic because they reside within vital structure (either intracellularly or intercellularly); efficient causes are extrinsic—they represent the entire spectrum of epigenetic processes, mechanisms, and events capable of being imposed on vital structures.

In biology, material cause is represented by all the levels of cellular and intercellular materials, without reference to any specific structural (anatomical) arrangement. Formal cause is the genomic code, i.e., a series of "rules" or "laws." These act at the molecular level to regulate the initial creation of the constituents of material cause. Efficient cause(s) are the epigenetic factors, as defined above, whose actions immediately regulate the next developmental branching point.

FOR AUTHOR USE ONLY

A metaphor is helpful. Consider the use of a computer to prepare this manuscript. The material cause is the hardware: the computers, printers, disks, and papers. The formal cause is the software: a specific word processing program, both its apparent, user-friend form and, in reality, its ultimate expression in machine language code. No combination of hardware and software could ever write an article. Extrinsic, epigenetic input is required, i.e., the composition and input of the text itself. Both intrinsic causes must be present before (prior to) the textual input, whereas the extrinsic, epigenetic typing is immediately (i.e., proximately) followed by creation, on the hard disk, of the text itself.

Both prior (intrinsic) and proximate (extrinsic) causes are necessary causes; neither alone is a sufficient cause for the creation of this manuscript. Only the two integrated together furnish the necessary and sufficient cause.

In ontogenesis, genomic (intrinsic, prior) and epigenetic (extrinsic, proximate) factors are each a necessary cause, but neither alone is a sufficient cause. Only the interaction of both provides both the necessary and sufficient cause of morphogenesis. This conclusion foreshadows the resolving synthesis of this dichotomy, presented in the companion article, which also contains the comprehensive bibliography.

"It is a fallacy that the genome, the totality of DNA molecules, is the main repository for developmental information; I.e. that there exists a genetic program, or blueprint, theoretically capable of creating an entire organism."

Biological Mechanisms and Processes: This article continues the dialectical analysis of the roles of genomic and epigenetic processes and mechanisms in the control of craniofacial growth and development. Previously a genomic thesis was outlined and several critical terms were defined. The dialectic process concludes here with an epigenetic antithesis and a resolving synthesis, following two additional definitions:

FOR AUTHOR USE ONLY

(1) A process is a series of actions or operations that lead toward a particular result. (2) A mechanism is the fundamental physical or chemical process(es) involved in, or responsible for, an action, reaction, or other natural phenomenon. That is, mechanisms underlie processes. For example, loading a femur is an epigenetic process: the possible resultant modification(s) of bone cell DNA (for example by methylation, or of chondrocytic DNA (for example as reflected in differential regulation of biosynthetic pathways, are epigenetic mechanisms. Similarly, the specific steps of the activation and deactivation of appropriate portions of the bone cell genome, associated with the trio of possible osteoblastic responses to loading (deposition, resorption, or maintenance of bone tissue) are further

examples of epigenetic mechanisms that control the genome. In this sense, the original versions of the functional matrix hypothesis (FMH) described only epigenetic processes, whereas recent revisions also described epigenetic mechanisms. The fundamental correctness of earlier FMH descriptions is supported by more recent research.

The Epigenetic Antithesis

Some of the principal strengths of this antithesis come from precise definitions of what a gene is and is not. For example: (a) "gene. The unit of heredity: one or more nucleic acid sequences incorporating information necessary for the generation of a particular peptide or RNA product"; and, (b) "enough is known about the genetic machinery [to know] that this is virtually the only kind of information which polynucleotide molecules are inherently capable of containing: nothing there at all about which proteins will be expressed in which cells at what time and in what quantities."

FOR AUTHOR USE ONLY

The genomic thesis is denied because it is both reductionism and molecular; that is, descriptions of the causation (control, regulation) of all hierarchically higher and structurally more complex morphogenetic processes are reduced to explanations of mechanisms at the molecular (DNA) level. For example, the genomic thesis of craniofacial ontogenesis passes directly from molecules to morphogenesis: directly from DNA molecules to adult gross morphology, ignoring the role(s) of the many epigenetic processes and mechanisms competent to control (regulate, cause) the large number of intervening, and increasingly more structurally complex, developmental stages particularly, and there are additional similarly reductionist views of odontogenesis.

The epigenetic antithesis, detailing both processes and mechanisms, is integrative, seeking to clarify the causal chain between genome and phenotype. Its goal is to identify and describe comprehensively the series of initiating biological processes and their related underlying (biochemical, biophysical) responsive mechanisms that are effective at each hierarchical level of increasing structural and operational complexity.

This article reviews some of the clinically significant epigenetic processes and mechanisms, existing at several organizational (structural, functional) levels, that regulate (direct, control, cause) cephalic and craniofacial (musculo- skeletal morphogenesis).

FOR AUTHOR USE ONLY

Craniofacial Epigenetics

"Broadly speaking, epigenetics refers to the entire series of interactions among cells and cell products which leads to morphogenesis and differentiation. Thus all cranial development is epigenetic, by definition." This view is supported here, despite continued expressions of genomic regulation of craniofacial morphogenesis.

As previously noted, epigenetic factors include

(1) All of the extrinsic, extraorganismal, macroenvironmental factors impinging on vital structures (for example, food, light, temperature), including mechanical loadings and electromagnetic fields

(2) All of the intrinsic, intraorganismal, biophysical, biomechanical, biochemical, and bioelectric microenvironmental events occuring on, in, and between individual cells, extra cellular materials, and cells and extra cellular substances.

In terms of clinical orthodontics, and of the FMH, all therapy is applied epigenetics, and all appliances (and most other therapies) act as

prosthetic functional matrices. Clinical therapeutics includes a number of epigenetic processes, whose prior operations evoke a number of corresponding epigenetic mechanisms. These latter, in turn, underlie the observed processes of tissue adaptations by both skeletal units and functional matrices.

Epigenetic Processes and Mechanisms

In craniofacial morphogenesis, more is known presently about processes than about mechanisms. Despite this, it is no longer sufficient to note, for example, that otherwise un-described epigenetic processes of "intrauterine environment" can regulate fetal mandibular growth. The future aim must be to elucidate the molecular, genomic, mechanisms whose activation underlies the adaptive growth processes of the mandibular functional cranial components (that is, of the mandibular skeletal units and their related functional matrices).

FOR AUTHOR USE ONLY

Loading

Many different epigenetic processes can evoke mechanisms capable of modifying DNA. At clinically significant structural levels, physical loading is unquestionably of the greatest importance. "Among the numerous epigenetic factors influencing the vertebrate face is mechanical loading." It is useful to consider the epigenetic process of loading and some of the epigenetic mechanisms this process evokes.

Loading per se. Loads may be imposed at many structural levels. While clinical observations usually are macroscopic, the loadings act microscopically, at molecular and/or cellular levels. Loadings are able to regulate several alternative molecular (cellular) synthetic pathways (mechanisms) of many tissues, including bone for example, the mechanical

environment is important in maintaining the differentiated phenotype of bone cells. It should be noted that loading may be dynamic (for example, muscle contraction) or static (that is, gravity); and to be effective, loads may increase, decrease, or remain constant.

Mechanical loading is known to influence gene expression. Of clinical (and FMH) interest, extrinsic musculoskeletal loading can rapidly change

(1) Both articular cartilage intercellular molecular syntheses and mineralization

(2) Osteoblastic (skeletal unit) gene expression. Epigenetic loading processes include gravitational variations that evoke unique mechanisms of molecular synthesis.

FOR AUTHOR USE ONLY

Extra cellular matrix deformation: Musculoskeletal tissue loading inevitably deforms an extra cellular matrix (ECM) that is not developmentally inert. Rather, in several ways, ECM regulates the formation, development, and maintenance of its included cells that synthesize the ECM. Further, ECM can regulate multicellular tissue morphogenesis and contribute to genomic regulation of its enclosed cells.

Cell-shape changes: Tissue loading can also alter cell shape. This inevitably deforms intracellular constituents, including the cytoskeleton. The epigenetic process of changing cell shape invokes the epigenetic mechanisms of **mechanotransduction** of biophysical forces into genomic and morphogenetically regulatory signals.

Cell-shape change processes can also activate several other epigenetic mechanisms, for example, stretch-activated ion channels in cartilage and

other mechanically initiated cell-signaling mechanisms. There is recent orthodontic interest in the cell-shape change of nonskeletal cells.

Cell-shape change may lead to nuclear shape deformation. This, in turn, is a mechanism that can directly cause (regulate) a consequent alteration of the mechanisms of genomic activity.

Epigenetic cell signaling processes: Several loading processes can regulate genomic expression. One, previously described, begins with cellular mechanoreception and mechanotransduction of the loading stimulus into an intercellular signal that undergoes parallel processing within a connected cellular network of bone cells. The details of cell-signaling are reviewed extensively elsewhere.

FOR AUTHOR USE ONLY

Chains of intracellular molecular levers: A second epigenetic cellular process begins with deformation of the ECM. This matrix has an epigenetic regulatory role in morphogenesis, by virtue of integrin molecules that physically interconnect the several molecular components of the intracellular (cytoskeletal) and the extra cellular environment (for cartilage). While the form (size and shape) of the cytoskeleton may be physically controlled by a broad spectrum of loadings, it responds identically to all.

The epigenetic mechanism evoked consists of a physical array of intracellular macromolecular chains, acting as levers, extending from the cell membrane to multiple specific sites on each chromosome. The molecular chain acts as an information transfer system between the extra cellular environment and the genome, transmitting signals generated by deformations of the ECM directly to the intranuclear genome. Indeed, such

informational transfer between cells and ECM is dynamic, reciprocal, and continuous.

Other processes and mechanisms: (1) DNA methylation is a potent epigenetic event. It is involved in many intracellular, extra cellular and intercellular mechanisms. It can "introduce novel features of cellular function far removed from the classical Mendelian view of the gene, chromosome, and inheritance with information flowing back to the DNA level and changing gene expression," the genome now being considered as a sophisticated response system and a carrier of information, a system activated by several epigenetic processes and mechanisms.
(2) There are numerous examples of yet other processes and mechanisms of epigenetic regulation of the genome.
(3) In addition, it has been shown that (botanical) epigenetic factors can impose metastable inheritable changes in the plant genome, a nontrivial matter not considered further here.

FOR AUTHOR USE ONLY

Epigenetic Regulation of Higher Structural Levels: In addition to the molecular and cellular processes and mechanisms noted, over a century ago the discipline of developmental mechanics (entwicklingsmechanik) established that the epigenetic process of extrinsic loadings play a major role in the regulation of bone tissue and bone organ growth, development, and morphology.

At the tissue level, there are several causal, strain-specific differences in bone tissue microstructure. Closely similar epigenetic mechanisms and processes are observed in the adaptation responses of all connective tissues, including cartilage, to loading.

At the organ level, the ability of the processes of motion and of articular function to regulate joint morphology is well-known and, of course, physical activity processes regulate organism skeletal adaptation responses. Other epigenetic processes affecting bone tissue include local vascular factors.

Regulation of functional matrices: Periosteal functional matrices are under closely similar epigenetic control. Mechanical loads regulate skeletal muscle (periosteal functional matrix) phenotype; and chronic muscle stimulation can change its phenotype. Numerous studies establish the neurotrophic role of neural innervations in muscle genome regulation. It remains only to note the truism that, for muscle as for bone, mechanical epigenetic factors, broadly termed function (or exercise) significantly control musculoskeletal growth, development, and maintenance of structural and physiological attributes.

A Resolving Synthesis

"It seemed that the next minute they would discover a solution. Yet it was clear to both of them that the end was still far, far off, and that the hardest and most complicated part was only just beginning."–Anton Chekov. (The Lady with the Dog)

As the epigraph indicates, it is certain that no matter what arguments, theoretical constructs, and supporting experimental data are presented here, the prevailing tension between the genomic thesis and epigenetic antithesis will continue unabated. Nevertheless, a resolving synthesis will at least clarify the bases for continued discourse.

The fundamental argument of this resolving synthesis, based on an analysis of causation, was presented earlier, and later amplified. It argues that morphogenesis is regulated (controlled, caused) by the activity of both genomic and epigenetic processes and mechanisms. Both are necessary causes; neither alone are sufficient causes; and only their integrated activities provides the necessary and sufficient causes of growth and development. Genomic factors are considered as intrinsic and prior causes; epigenetic factors are considered as extrinsic and proximate causes. The data supporting this synthesis are provided here and above.

It is acknowledged that the validity of this dialectic synthesis is significantly dependent on the validity of its epigenetic antithesis. In turn, a defensible epigenetic antithesis should convincingly suggest some process(es) and/or mechanism(s) that can regulate (direct, control, cause) morphogenesis. It is argued here that these are provided by the newly emerging disciplines of complexity.

FOR AUTHOR USE ONLY

Complexity and self-organization: The theories of ontogeny and phylogeny currently are being significantly reinvigorated by the new and evolving science(s) of complexity that integrate topics from mathematics (for example, cellular automata, fractals, strange attractors), biology (for example, genetic algorithms, artificial life simulations, neural networks, emergence, adaptive systems, connectivity), and physics, while minimizing distinctions between them. Complexity theory (CT) also integrates specifically related topics in bioengineering and the computer sciences; for example, chaos, information, and hierarchical theories, fuzzy logic, as well as cyto (tissue) mechanics and molecular (nano) mechanics.

Because epigenetic processes and mechanisms are best explained as examples of CT, a clear-cut demonstration of the role of CT in craniofacial ontogeny, at some point, is both necessary and possible. But in this place only this brief, intuitive preview is possible. Because fairness to both the novelty and conceptual richness of CT requires a comprehensive presentation to make it generally intelligible, it will be substantively reviewed subsequently.

CT provides descriptions of the behavior of complex biological systems that exist as "ensembles" of several tissues and organs, and not as clusters of individual cells and extra cellular substances. Such an ensemble (identical to a functional cranial component in the FMH) is termed here as a complex adaptive system (CAS), structurally arrayed as a vital continuum. This term is defined here as it is in the several analytical finite element methods (FEM) recently introduced into orthodontics and physical anthropology.

FOR AUTHOR USE ONLY

CT provides compact, statistical descriptions of the collective growth behavior of such CAS continuity. During ontogeny, vital CAS exhibits the creation of robust, spontaneous, and emergent order.

An algorithm for control of such a CAS requires that it is able to alter itself in response to the (epigenetic) information produced by the system it is trying to control. In a CAS, minor changes in the epigenetic input can cause huge fluctuations in the morphological output.

CT, as it utilized information theory, assumed that a CAS processes information (both genomic and epigenetic) in a parallel, not a serial, manner. Where most previous biological theories of development were based on the methods of deterministic (genomically predetermined), classical mechanics, information theory, and CT, are probabilistic (epigenetically self-organized

and emergent), and are based on the methods of statistical mechanics. It is probable that ontogeny involves nonlinear processes and is not fully predictable; that is, growth and development, to a significant extent, exhibit both random behaviors and frequent perturbations. To clarify this point, note that previously most biological models were studied as if they were linear. That is, when their mathematical formulas were graphed they looked like straight lines. Linear systems are predictable: the calculus shows the changes in their state, and statistics (especially regression analysis) reduces their data to a line. However, CT makes it clear that most biological systems are nonlinear and are not most correctly described by these mathematical techniques; nonlinear formulations are necessary.

The highly ordered morphological properties of adult complex biological systems (for example, functional matrices and skeletal units) result from the operation of a series of spontaneous and self-organized ontogenetic processes and mechanisms. Such emergent self-organizing events can create phenotypic variability under constant genetic and other extra organismal epigenetic conditions.

FOR AUTHOR USE ONLY

CONCLUSION -

Integration of pertinent advances in biomedical and bioengineering permitted an ongoing revision of the functional matrix hypothesis. The first two articles in this series, by emphasizing the roles of a number of biophysical and biochemical factors in the regulation of morphogenesis, implicitly argued for the correctness of the fundamentally epigenetic thrust of the FMH. However, because the conceptual tension between hypotheses suggesting the regulatory primacy of either genomic (genetic) or of epigenetic factors and/or processes in morphogenesis continues

unabated, it seemed useful to reevaluate this nontrivial matter, using the dialectical method of presenting a thesis, an antithesis, and a resolving synthesis.

INTRODUCTION

As early as 1000 BC attempts have been made to treat malocclusions. Appliances to move teeth have been found in Greek and Etruscan excavations. Aulius Cornelius celsus (25 BC – 50 AD) advocated the use of finger pressure to align the teeth as active treatment for correction of malocclusion.

Pierre Fauchard, the father of Modern Dentistry, is generally given the credit for the first comprehensive discussion of "Regulating teeth". In his treatise on Dentistry, published in 1728, he discusses the "Bandelette", now called the expansion appliance.[1]William E Magill (1823-1896) was the first person to band teeth for active tooth movement in 1871.[2]It was during this period (1855-1930) where orthodontics saw a new era with the introduction of brackets. In orthodontics, bracket is a sort of attachment bonded to enamel, that provides the means to transfer the force applied by the arch wire to the tooth in the proper, precise and effective manner. The evolution of this appliance, originally manufactured from stainless steel, has demonstrated a unique progress curve characterized by extended quiescent periods interspersed with notably active periods.[3]

The original treatment approach utilized a slot attached to a stainless steel band that was cemented to the tooth, and early attempts to modify this attachment resulted in wide base surfaces onto which a slot was soldered. This appliance was then bonded to the tooth with epoxy resin. It was in the late 1970's that direct bonding to enamel was widely accepted as a standard procedure to replace banding.

FOR AUTHOR USE ONLY

In orthodontics, all of the devices that project horizontally to support arch wires could be called as brackets. However due to differences in design and application the term is used only when referring to those devices that are open on one side usually on vertical or horizontal plane.

The term "Bracket" came into use in orthodontics when Dr. Edward .H. Angle introduced the Ribbon Arch appliance in 1916. This bracket is attached to the band close to its gingival margin and has a vertical slot facing occlusally.

As the need for horizontal, one directional placement and simultaneous engagement of all teeth became apparent Dr. Angle changed and rechanged bracket designs and evolved the edgewise bracket. This edgewise arch appliance is the last of the many contributions of Dr. Angle and was introduced to the profession by one of his last students Dr. Allen G Brodie, Sr. in 1928.

FOR AUTHOR USE ONLY

After the death of Angle, this did not mark the end but saw a new beginning, which resulted in the evolution of different bracket systems. Some of the contributions were Steiner, Holdaway, Jarabark, Fizell, Ricketts, Tweed and many others.[1]

During the middle of the last century and a half the orthodontic profession had been stirred rather profoundly by the theories and new technique of Dr. P.R. Begg of Adelaide, South Australia. In Begg's differential force technique, modified ribbon arch type bracket with the slot facing gingivally is used with light round wires.

From time to time, a number of workers advocated the use of various types of bracket angulations to achieve built in tooth movement. Andrews in 1970, with the concept of slot angulation to its logical conclusion introduced the completely preadjusted straight wire appliance (SWA).

In 1979, Dr. Ronald Roth introduced a bracket set up containing modifications of the tip, torque, rotations and in-out movements of Andrews standard set up brackets. A number of modifications of the bracket prescriptions were made in the coming years. Self-ligating and Combination brackets were also introduced to improve the efficacy of treatment mechanics.

The design of the brackets is one of the important factors for efficient tooth movement and control of the complex force system acting when an appliance is worn by the patient. There are a large number of bracket designs meant to effect various tooth movement such as tipping, translation and torque. These brackets form the basis of all the orthodontic appliances.

The next stage of bracket evolution included modification of the base design to provide higher bond strengths with adhesives, while concurrent efforts focused on decreasing the base surface areas, which at that time covered almost the entire labial mesiodistal tooth surface.[3]Apart from these variations in designs, brackets also differ in the material. Brackets may be manufactured from stainless steel, Gold, Titanium, Cobalt-chromium, Polycarbonate and Fibre glass, Ceramic, Magnetic and metal reinforced plastic brackets. These brackets vary in certain factors such as bond strength, friction and fracture resistance. Brackets also vary in their dimensions and slot size. These factors influence treatment mechanics to a great extent.Thus, the wave of bracket design changes continues to mount, as varieties of brackets are available. The armamentarium of brackets for the present day orthodontist is formidable.

This is an attempt to review the journey of evolution of brackets and its current trends.

FOR AUTHOR USE ONLY

CLASSIFICATION OF ORTHODONTIC BRACKETS

I) Based on the attachment to the tooth surface :

A) Weldable

B) Bondable

1. Laminated mesh
   - Regular
   - Mini
   - Open mesh
2. Porous powder
3. Honey comb - microlock
4. Chemically treated

II) Based on material constituent :

A) Stainless steel

B) Polycarbonate

C) Fiber glass reinforced

D) Ceramic

1. Alumina based
   - Monocrystalline
   - Polycrystalline
2. Zirconia based brackets

E) Titanium brackets

F) Magnetic brackets

G) Cobalt-chromium brackets

H) Composite brackets

FOR AUTHOR USE ONLY

III) Based on technique :

A) Begg light wire bracket

B) Edgewise bracket

C) Straight wire bracket

D) Brackets used in combination technique

E) Universal bracket

F) Twin wire bracket

G) Bracket*s* used in BEDDTIOT

H) Tip-Edge bracket

I) Brackets used in Vari-Simplex Discipline

J) Brackets used in lingual orthodontics

IV) Based on bracket arch wire contact:

Ligating brackets

A) Self ligating brackets

1. Swirl lock bracket
2. Ford lock bracket
3. Slide pin bracket
4. Russel lock bracket
5. Edge lock bracket
6. Speed bracket
7. Activa bracket

V) Based on bracket manufacturing process

A) Milled bracket

B) Casted bracket

C) Moulded and sintered bracket

FOR AUTHOR USE ONLY

EVOLUTION OF THE EDGEWISE APPLIANCE

Before the Angle system came into existence, orthodontics was being practiced in a highly individualistic manner. There were hundreds of different ways to treat patients, which began nowhere and ended nowhere. During this time the practice of orthodontics was in a chaotic condition.

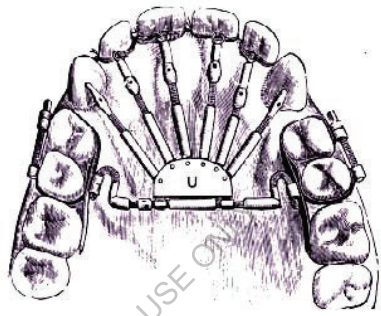

Fig. 11-2 An appliance used before the Angle system, often referred to by Dr. Angle as a monstrosity. (From Angle EH: *Treatment of malocclusion of the teeth*, Philadelphia, 1907, SS White Dental Manufacturing, p. 176.)

FOR AUTHOR USE ONLY

There was a definite need to develop a standard appliance for precise tooth movements.[4]

Pierre Fauchard, a French physician in 1798 made the first attempt to move teeth. This appliance consists of a flat strip of metal, pierced with suitable holes to pass the wires to be tied around the crooked tooth. The metal strip was formed into an arch type which concurrently applied force after tying. Anchorage employed was simple anchorage and simple tipping movement was possible.[4]

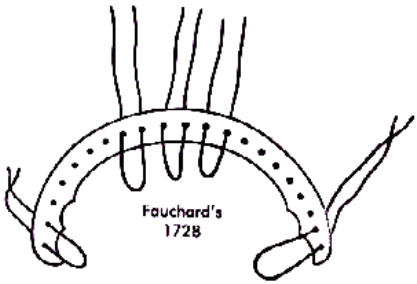

Fig. 11-3 Pierre Fauchard's orthodontic appliance. 1728. (From Angle EH: *Treatment of malocclusion of the teeth*, Philadelphia, 1907, SS White Dental Manufacturing, p. 196.)

In 1847, in New York, Dwinelle invented the regulating jack screw.

Fig. 11-4 Dwinelle's jack-screw, 1849. (From Steiner CC: *The Angle orthodontist*, Brooklyn, NY, 1933, E.H. Angle Society of Orthodontia, p. 281.)

FOR AUTHOR USE ONLY

It delivered a pushing force on the teeth, which was later improved by Dr. Edward Hartley Angle to increase the range of action. During this time Angle developed the regulating retraction screw.[4]

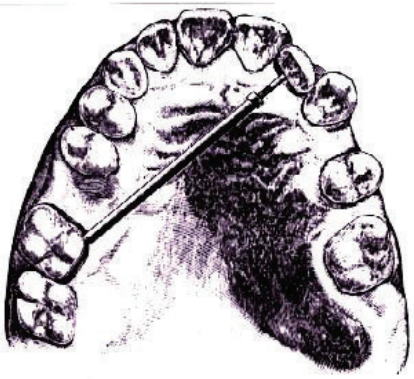

Fig. 11-5 Angle's jack-screw. (From Goddard CL: *The American text book of operative dentistry*. Philadelphia, 1897, Lea Brothers, p. 580.)

Fig. 11-6 Angle's jack-screw. (From Goddard CL: *The American textbook of operative dentistry*, Philadelphia, 189?, Lea Brothers, p. 567.)

FOR AUTHOR USE ONLY

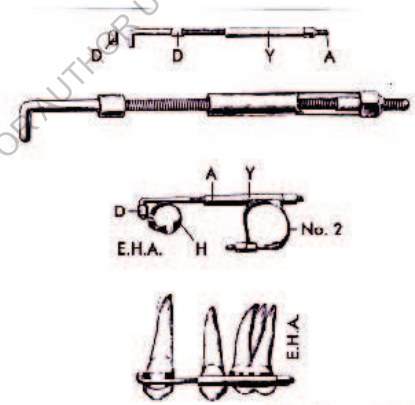

Fig. 11-7 Angle's retraction screw, 1887. (From Angle EH: *Treatment of malocclusion of the teeth*, Philadelphia, 1907, SS White Dental Manufacturing, p. 186.)

In 1887, Angle developed the prototype of the first bracket attachment (a delicate metal tube soldered to the band). Due to many technical problems and frustration in treatment, he was motivated and inspired to

develop a standard appliance which incorporated five important properties[4].

The appliance must be:

Simple → must push, pull and rotate teeth.

Stable → must be fixed to the teeth

Efficiency → must be based on Newton's third law and anchorage.

Delicate → must be accepted by the tissues and must not cause tissue inflammation and soreness.

Inconspicuous → must be esthetically acceptable.

With few exceptions the appliances used in contemporary orthodontics are based on Angle's designs from the early 20th century.

Angle developed four major appliance systems.

I. THE E ARCH APPLIANCE (1907)[4]

In the late 1800s, a typical orthodontic appliance depended upon some sort of a rigid framework to which the teeth were tied so that they could be expanded to the arch form dictated by the appliance. The E- Arch which was introduced in 1887, was a modification of this basic design.

APPLIANCE DESIGN

Clamp bands were used in the appliance construction. These clamp bands consisted of a metal band that nearly encircled the tooth crown. Each end was bent outward abruptly, perforated and thickened. The perforation in one flange was threaded, and a screw passed through it. The shaft or screw when turned, tightened the band around the tooth.

Clamp bands were placed only on the molars, and a heavy labial arch wire extended around the arch. The end of the wire was threaded, and a small nut placed on the threaded portion of the arch allowed the arch wire

FOR AUTHOR USE ONLY

to be advanced so that the arch perimeter increased. Individual teeth were simply ligated to this expansion arch. If molar expansion was desired, the archwire was expanded.

TYPES OF E- ARCH APPLIANCE:

a) Basic E-arch: Used in the mandible with Bakers anchorage.

b) Ribbed E-arch: Used in expansion by tying brass ligatures to the arch.

c) E-arch without threaded ends: This fits into the molar sheaths with an attached ball for the high pull head gear in the incisor area.

d) E-arch with hooks: These are used in the maxilla. The entire maxillary dentition was moved distally and the mandibular dentition was moved mesially by the action of inter maxillary elastics. This approach also had a maxillomandibular growth guidance effect which was recognized later.

FOR AUTHOR USE ONLY

ADVANTAGES OF THE APPLIANCE:

- Simplicity of construction

SHORTCOMINGS OF THE APPLIANCE:

- It could deliver only heavy interrupted force.
- It was capable of only tipping teeth.
- It was not able to precisely position any individual tooth.

To overcome these difficulties, the Pin and Tube appliance was introduced by Angle.

II. PIN AND TUBE APPLIANCE (1910)[4]

This was the first appliance that employed a bracket and used bands on most of teeth.

APPLIANCE DESIGN:

Bands were placed on all the teeth and a vertical tube was placed on each tooth into which a soldered pin from a smaller arch wire was placed. With this appliance, tooth movement was accomplished by repositioning the individual pins at each appointment.

ADVANTAGE OF THE APPLIANCE:

This was the first appliance with mechanism for root movement.

SHORTCOMINGS OF THE APPLIANCE:

- An incredible degree of craftsmanship was involved in constructing and adjusting the pin and tube appliance.
- Although this appliance was theoretically capable of great precision in tooth movement, it proved incapable in clinical use.
- It is said that Angle himself and one of his students ever mastered the appliance.
- The relatively heavy base arch meant that spring qualities were poor, and the problem therefore was compounded because many small adjustments were needed.
- The pins had to be expertly soldered, fitted perfectly into the tubes on the bands, removed, moved along the archwire, soldered again and fitted once more into tubes on the band.

FOR AUTHOR USE ONLY

- Axial inclinations of the pins had to be altered and square ends of the archwire had to be fitted properly into square tubes on the molar bands.
- Patients were required to come for activations every few days.
- The appliance made rotational adjustments most difficult.

III. RIBBON ARCH APPLIANCE (1915)[4]

Angle's next appliance modified the tube on each tooth to provide a vertically positioned rectangular slot behind the tube. This appliance was introduced in 1915 due to difficulty in the use of pin and tube appliance.It was actually the first bracket, as such, to be used in an orthodontic appliance.

FOR AUTHOR USE ONLY

APPLIANCE DESIGN:

-It was characterized by Bracket with a vertical slot and the arch wire was held in position by Brass pins.

- The teeth were free to move along the arch wire like a string of beads.

ADVANTAGES OF THE APPLIANCE:

- The archwire was small enough to have good spring qualities and was quite effective in aligning individual malposed teeth.
- The appliance had force control and a degree of stationary anchorage.
- It allows rotations to be accomplished readily.
- It offers control of buccolingual and labiolingual movements, and both incisogingival and occlusogingival movements are possible.

SHORTCOMINGS OF THE APPLIANCE:

- One of the important shortcomings of the ribbon arch appliance as originally developed, was that it made mesiodistal axial movements

difficult to obtain because anterior teeth could only be retracted at the expense of the anchorage provided by the posterior teeth.

- Although the ribbon arch wire could be twisted as it was inserted into its slot, the major weakness of the appliance was that it provided poor control of root position. The resiliency of the ribbon arch appliance simply did not allow generation of moments necessary to torque roots to a new position.
- The appliance was not suitable for en masse movements.
- Mesial and distal tipping bends could not be incorporated in the archwire and premolar teeth could not be moved bodily.

IV. THE EDGE WISE APPLIANCE:[4]

Two years before he died, with the knowledge born from experience and gained from his other appliance inventions, Angle set out to develop an appliance to overcome the difficulties of the previous appliances.

FOR AUTHOR USE ONLY

The Edgewise appliance was Dr. Angle's final and greatest contribution to orthodontics. He changed the form of the brackets by locating the slot in the center and placing it in the horizontal plane instead of a vertical plane and inserted a rectangular wire rotated 90 degrees to the orientation it had with the ribbon arch- thus the name 'edgewise'. The new edge wise bracket consisted of rectangular box with 3 walls within the bracket, 0.022 inch by 0.028 inch in dimension. Its slot opened horizontally. This new design provided more accuracy and thus a more efficient torquing mechanism.

The Edgewise arch mechanism was designed to allow the orthodontist to place teeth in Angle's concept of "line of occlusion",

which is stated as ‘the line with which in form and position according to the type, the teeth must be in harmony, if in normal occlusion.’

Angle believed that there could be only one true line of occlusion and it must be the same as the architectural line on which dental apparatus were constructed. The ideal line was intended to govern the length, breadth, and peculiar curve of the dental arches along with the size and pattern of each tooth cusp and inclined plane comprising these arches. The unique contribution of the edgewise appliance in attaining a balanced occlusion is complete control over axial inclinations of all teeth in all directions. The classical mechanical means for exercising this control is the engagement of the archwire in the slot of the bracket on the tooth as shown below.

FOR AUTHOR USE ONLY

MODIFICATION OF THE ORIGINAL EDGEWISE BRACKET

1. ORIGINAL SINGLE WIDTH EDGEWISE BRACKET[5]**:**

- The original edgewise bracket as designed by Angle was made of soft gold with a 0.022x0.028 inch slot that was readily deformed by the forces of occlusion and by tying ligature wires to the bracket.
- The bracket was 0.050 inch wide and soldered to the gold band material.
- Arch wire did not rest against the surface of the orthodontic band but only on the bottom of the bracket slot.

DISADVANTAGES OF THE SINGLE WIDTH BRACKET:

- Because of narrow width involved, the bracket itself was ineffective for tooth rotation.

  To overcome this problem, Angle soldered gold eyelets at an appropriate position on the orthodontic bands. Ligature wire tied from the eyelet to the arch wire rotated the tooth by means of deflection of the archwire and compression of the periodontal ligament.

FOR AUTHOR USE ONLY

DISADVANTAGES OF THE EYELETS:

- Repeated tying of the eyelets was necessary to rotate the tooth to its final position.
- It was necessary to continue tying the eyelets throughout the treatment plan to prevent any relapse of rotation thus making the procedure time consuming and inefficient

2. TWO SEPARATE BRACKETS ON A SINGLE TOOTH[5]:

The next step in the development of the present day edge wise bracket began with the use of the two brackets on a single tooth spaced in a way that they would effect rotation of the tooth.

DISADVANTAGES OF TWO SEPARATE BRACKETS :

- Extreme care had to be taken to place the slots of the brackets in perfect alignment; otherwise, the archwire could not be seated into both the brackets.

3. TWIN BRACKETS [5]:

- The next step in the development was joining together of the two edgewise brackets on a common base.
- These were named as "Siamese twin brackets" by Brainerd Swain, the originator of this bracket.
- The space between the two brackets was 0.050 inch, equal to the width of one of the brackets.
- It gained popularity for use on upper central incisors and on molar teeth.
- The success of the early Siamese twin bracket led to the development of Siamese twin brackets that were not as wide as the original and were termed as the "Twin brackets".
- Basically there are four sizes of twin brackets:
  - Extra wide
  - Standard
  - Intermediate
  - Junior

POSTERIOR BRACKET[5]:

FOR AUTHOR USE ONLY

- Another early development was the evolution of a solid bracket that was approximately twice as wide as the original edgewise bracket called a posterior bracket. Fig. 9.10
- It was approximately 0.100 inch wide and although designed to be used on molar teeth, it had gained popularity for use on practically all teeth.

4. CURVED BASE TWIN BRACKET[5] :

- The next evolutionary step was curving of the base of the twin bracket to reduce the deflection of the bracket from the base on teeth with curved contours of the buccal surface.
- These brackets conform to the buccal surfaces of the canines and premolars. Fig. 9,11.

FOR AUTHOR USE ONLY

ADVANTAGES OF THE TWIN BRACKET:

- Main advantage was its ability to effect most of the tooth rotation without the use of auxiliary eyelet ties.
- Maintain control of axial tooth inclinations.
- "*Positive control*" which means that once the tooth has been rotated the mere tying of the bracket with ligature wire maintains the tooth in its corrected position. Thus a relapse of rotation is prevented and at the same time, the teeth that originally were not rotated are also prevented from rotation during space closing and retraction procedures.

DISADVANTAGES OF THE TWIN BRACKET :

- Interbracket span i.e the length of the archwire between brackets is decreased with the increased width of the twin bracket.
- Resiliency of the arch wire is decreased.
- Difficulty in employing closing loop archwires and second order bends because if the archwire is to slide posteriorly during activation of the closing loops, the decreased interbracket span interferes with the amount of closing action that can be obtained.
- Difficulty in obtaining final 10% of tooth rotation.

5. LEWIS BRACKET[5] :

- During the development of twin brackets, another approach to the problem of efficient tooth rotation was developed by Dr. Paul D Lewis, who soldered auxiliary rotation arms that abutted against the bracket itself and thus offered a lever arm to deflect the arch wire and rotate the tooth.
- The present Lewis rotation bracket is a one piece bracket with integral rotation wings. It is equivalent to the original edgewise bracket but, the tooth rotation deficiency of the latter is overcomed, while the "single width" feature is maintained.

FOR AUTHOR USE ONLY

ADVANTAGES OF THE LEWIS BRACKET :

- The rotation wings on the Lewis bracket do not interfere with occlusogingival deflections of the archwire and therefore do not decrease the working interbracket span.
- They do not interfere with the activation of closing loops, second order bends and other arch wire fabrications that slide freely past the rotation wings.

- One decided advantage is 100% tooth rotation can be easily obtained and over correction of rotations is also possible. This can be accomplished by bending one wing closer to the tooth and the opposite wing farther away. Fig. 9.29.

DISADVANTAGES OF THE LEWIS BRACKET :

- Less control of axial inclination of tooth than to do twin brackets.

6. ANTI TIP LEWIS BRACKET :

- Incorporated Notches / slots in the ends of the wings of the brackets.
- Can be easily tied and is quicker.
- Deflection of the arch wire is quick effecting rotation of the tooth.

FOR AUTHOR USE ONLY

7. VERTICAL SLOT LEWIS BRACKET [5]:

- A refinement in the Lewis bracket has been the incorporation of 0.020x0.020 inch vertical slot.

ADVANTAGE OF THE VERTICAL SLOT:

- Possible to use uprighting springs to correct axial inclination of the tooth adjacent to extraction spaces.

8. CURVED BASE LEWIS BRACKET[5]:

- This involved the curving of the base and wings of the bracket to conform to the canine and premolar teeth.

ADVANTAGE OF CURVED BASE LEWIS BRACKET:

- It allows greater contact with the band or bonding pad.
- The wings lie close to the tooth for most of their length, which reduces trapping of food around the wings.

9. STEINER BRACKET[5]:

- This was introduced shortly after the Lewis bracket and was designed by Cecil Steiner.
- These bracket incorporated flexible rotational arms and therefore did not depend entirely on the resiliency of the archwire for tooth rotation.
- Steiner bracket utilizes a single width edge wise bracket and therefore has the inherent advantage and disadvantage of this type of appliance.
- It is easy to tie and is quite efficient for tooth rotation. It works satisfactorily as long as the flexible arms do not undergo permanent deformation. Once a permanent deformation of the arms has occurred, complete rotation will not be effected unless the arms are readjusted to their original position.

FOR AUTHOR USE ONLY

11. BROUSSARD BRACKET[5]:

- Designed by Garford Broussard for use in the Broussard technique.
- Modification of the edgewise bracket in which there has been the addition of a 0.0185x0.046 inch vertical slot to accept a doubled 0.018 inch auxiliary wire.

BURSTONE'S SEGMENTED ARCH TECHNIQUE

Segmented arch technique is a modified, full-banded edgewise orthodontic procedure which uses relatively light, constant force, with control over anchorage units as well as teeth to be moved. It was developed by Dr. Charles J. Burstone and Dr. James Baldwin in 1961.

It differs from therapy with continuous arches in that it consists of multiple wire cross sections so that varying wire sizes may be found in different portions of the arch.

Segmented arch technique set-up consists of[6]:-

- Wide Siamese brackets on the incisors.
- BURSTONE'S CUSPID BRACKET:
  - Consists of a basic 0.022 x 0.028 edgewise slot
  - Additional 0.017 x 0.025 vertical auxiliary tube placed gingivally for attachment of retraction springs.
- Bracket- tube combinations on bicuspids with the tube placed occlusally.
- Upper first molars carry a triple bracket tube combination consisting of:
  - 0.022 x 0.028 inches slot
  - 0.045 inches headgear tube
  - 0.017 x 0.025 inches horizontal auxiliary tube placed gingivally
- Lower first molars carry a double bracket tube combination consisiting of:
  - 0.022 x 0.028 inches bracket
  - 0.017 x 0.025 inches horizontal tube placed gingivally

FOR AUTHOR USE ONLY

- Second molars carry a single 0.022 x 0.028 inches horizontal tube.
- Horizontal lingual sheaths on all first molars to accept a doubled over 0.036 inch wire.

UNIVERSAL APPLIANCE

The Universal Appliance was developed by Dr. Spencer R. Atkinson in 1928. It has undergone periodic refinements up to this day, keeping up with changing techniques, without losing its essential characteristics. In this technique there is no standard protocol to be followed in all cases. The needs of each individual case will determine which separate part or combination of elements may be used. The variety of combinations available with the Universal Appliance are many, and their proper selection will depend on the operator's good judgment.

It is essentially a labial and lingual type of appliance whose main elements are the bracket and the lingual arch, with contraction coil springs playing a very important role[7].

FOR AUTHOR USE ONLY

THE UNIVERSAL BRACKET[7]:

The fundamental element is the Universal bracket, a combination of the edgewise principle and Angle's ribbon arch. This bracket gives the appliance control in three planes of space. This bracket seems to be ideal for orthodontic mechanics because of its versatility and its reduced size.

A very popular Universal bracket is called the "double action bracket". It has two transverse slots.

- The gingival or horizontal slot, into which an .008" up to an .014" round wire may be fitted, opens buccally. This slot controls the

mesiodistal inclinations and serves as a fulcrum for labio-lingual movements.

- The incisal slot is vertical and opens incisally, similar to Angle's ribbon arch bracket or Begg's light wire bracket. It will hold round wires from .008" up to .016" or flat wires from .008" .020" up to .015" .028". This slot controls the tooth bucco -lingually and also controls rotations. Both slots allow the tooth to move bodily during retraction.

- This bracket has a precurved base for better adaptation and is available in two sizes, a long one with a body height of .150" and a short one of .125".
- Both the gingival and the incisal wires are locked into the bracket by a single lock pin or by an .008" or .010" soft stainless steel ligature wire. The turned end of the lock pin or the pigtail of the ligature wire are tucked alongside the lateral tabs of the bracket to protect the soft tissues. These tabs are used to control correction of mesio-distal inclinations.

FOR AUTHOR USE ONLY

- A variation of this bracket is the "root torquing bracket". Its tabs are an eyelet type which extend outward permitting extra ligation for severe rotations, extra leverage, and better support for the archwires. It is used mainly for wide teeth or severely rotated teeth. It also comes in two sizes and has a precurved base[7].

LIMITATION OF THE ORIGINAL UNIVERSAL BRACKET[8]:

- Problems of post treatment stability.
- The lateral extending tabs or wings were too bulky .
- The central vertical shaft was too narrow and shallow to accomodate the archwires and pins or ligatures comfortably.

The solution, then, was to eliminate the lateral extending wings and to make a bracket that was wider mesiodistally with more room buccolingually[8].

- These modifications would provide the Universal Appliance with a simple, practical bracket with greater built-in leveling, rotating and torquing potential and with more room for ligating or pinning.
- There would also be enough room for an auxiliary attachment such as an uprighting spring or for extra ligatures.
- Elimination of the lateral wings would provide the welding tabs with more welding space and, due to the width of the whole bracket, the forces applied to it would be distributed in a wider area, making the bracket more efficient and comfortable to work with.

FOR AUTHOR USE ONLY

THE 3-D UNIVERSAL BRACKET[8]:

The next step towards evolution was to design a bracket with such specifications and to submit it to clinical test to prove its performance. The result was the latest Universal bracket called the 3-D Universal Bracket due to its tridimensional mechanical principle.

- This bracket is essentially a vertical hollow shaft with two lateral welding tabs. The central shaft has two slot openings.

- The horizontal one opens labially at the gingival third and will accomodate .008″ up to .016″ round wire.
- The vertical slot opens incisally near its base and extends gingivally one-third of the bracket height. It will accomodate a single wire, a double wire, a twisted bundle of round wires, or a single ribbon or flat wire ranging from .008″ .020 ″ up to .016″ .028 ″.
- The two curvatures of the base of the bracket provide a smooth adaptation to the band and to the surface of the teeth.
- Compared to one of the most frequently used Universal brackets, the 3-D Universal Bracket is wider mesiodistally and slightly deeper buccolingually. It has no extending or curling lateral tabs.

FOR AUTHOR USE ONLY

ADVANTAGES OF THE 3-D UNIVERSAL BRACKET[8]:

1. Efficiency in leveling and correcting rotations and mesiodistal axial inclinations.
2. Permits bodily movement of teeth in a mesiodistal direction.
3. Retracts canines without tipping.
4. Torques automatically in most cases. Individual torque is also easily achieved.

Comparison of previous Universal bracket with the 3-D Universal Bracket.

B and BB, incisal view.

C and CC, side view.

D and DD, the areas of torque application (shaded).

TWIN WIRE APPLIANCE

It was introduced by Joseph Johnson in the 1930's. The philosophy behind its use was that by virtue of *two* light wires placed in the same bracket, more physiologic tooth movement can be obtained than with *one* heavy wire.

The twin wire attachment and bracket permit rapid reduction of rotations with relatively little discomfort to the patient[9].

The twin wire appliance consists of:

I. Twin labial arch[10]:

- It is composed of two end tubes into which a doubled, fine, stainless steel wire is drawn.
- The end tube is made of stainless steel with an outside diameter of 0.036″, inner diameter is 0.022″ and is 1 1/8″ in length.
- A hook is soldered to this tubing when intermaxillary elastics are to be used.

II. Cap and channel bracket[10]:

- It consists of a locking device which is attached to the labial surface of the bands to be cemented to the teeth.
- This locking device is composed of a male and a female part.
- The male part is welded in the middle of and parallel to the edges of the bands. It has parallel walls forming a channel in which the twin wires are to be seated and the outside walls are dovetailed.
- The female part which is called a cap, slips over the male part and is held in place by friction.
- The locks are 1/8″ long and 1/16″ wide and 1/32″ thick and streamlined in shape.

FOR AUTHOR USE ONLY

LIMITATION OF THE TWIN WIRE APPLIANCE[9]:

- Problem of anchorage.
- Lack of control of canine and premolar teeth after correction of rotations.

Today the twin-wired appliance finds less use in orthodontic speciality circles, largely because of its non-extraction orientation and greater difficulty in controlling teeth and achieving torque when teeth have been extracted.

BIOPROGRESSIVE THERAPY

This technique was introduced by Dr. Robert Ricketts and Dr. Ruel Bench in 1950's who combined contemporary edgewise mechanics with solid diagnostic principles and an innovative approach to sectional mechanics. This method may be considered an evolution from the original edgewise technique, with features of certain light-wire methods incorporated.

FOR AUTHOR USE ONLY

BRACKET MODIFICATION BY RICKETTS[11]:

- Increased mechanical efficiency was desired over the staple, used in the original edgewise, for rotation correction.
- Ricketts designed a wide-flanged easy-tie 0.018" x 0.030" Siamese bracket for:
    1. Ease of ligating
    2. Uprighting access
    3. Flexibility of the elastic attachment

- This design was an evolution from the original Steiner design and the narrow slot was developed in consultation with Steiner and Lang.
- The bracket could be fabricated on bands or bonded directly.

DEVELOPMENT OF THE BIOPROGRESSIVE SET-UPS[11]:

There are three combinations of the bioprogressive set-up which use the basic bioprogressive percepts:

1. STANDARD BIOPROGRESSIVE:

- In the standard bioprogressive setup torque was built into the brackets of the upper central and lateral incisors as well as all four cuspids.
- The torquing of the lower buccal segment and step bends in the arch for the premolars and molars were relegated in the arch wires.

FOR AUTHOR USE ONLY

2. FULL TORQUE BIOPROGRESSIVE:

- In this setup torque combinations were developed for the lower premolars and molars.
- Rotation tubes were placed on lower molars.
- Lateral step bends were needed, and even the bends were already placed in the preformed archwires.
- All torque requirements were eliminated from the wire except for the variations needed.
- First-order activations were avoided because of the need for bulking-up of the brackets, the danger of esthetic and hygienic

complications, and the need to prevent lever action against the band itself.

3. TRIPLE CONTROL BIOPROGRESSIVE:

- This setup combines the first order offset bends with the second order tip, and the third order torque, to present the complete "triple control" needed to place the teeth in all three planes of space to accomplish the necessary movements needed to reach the objective of the overtreated orthodontic occlusion.
- To accomplish this first, all the canine brackets were raised to produce the buccal step for the first premolars.
- Second, because the molar needs to be stepped bucally from the second molars and in order to obviate the step in the wire, the second premolar was raised so that it will be aligned lingually.
- This allows a continuous arch to be used as the final ideal finishing arch. With the Triple Control appliance, the finishing archwire does not require the offsets or torque, since they are now built into the appliance.

FOR AUTHOR USE ONLY

APPLIANCE DESIGN[11]:

A) PROVISIONS FOR TIPPING(Second-order control)

All bands receive brackets parallel to the band margin except the following:

Upper lateral incisor	8° down on distal
Upper Canine	5° down on distal

Lower Canine	5° down on distal
Lower first Molar	5° down on mesial

B) PROVISION FOR TORQUE(Third-order control)

- For standard, full torque and triple control bioprogressive setup:

Upper Central Incisor	22° (root to palatal)
Lateral Incisor	14° (root to palatal)
Canines	7° (root to palatal)
Lower Canines	7° (root to lingual)

(For standard, full torque and triple control)

- For full torque & triple control bioprogressive setup:

Lower Second Premolar	14° (root to buccal)
Lower 1st Molar	22° (root to buccal)

FOR AUTHOR USE ONLY

C) PROVISIONS FOR ROTATIONS & STEP OUTS

- Standard & full torque bioprogressive setup:

Lower Molar	12° (to the distal)

Rotation:

i) Ligation to eyelet, when simple bracket used.

ii) Figure of eight ligature ties for reciprocal rotation.

iii) With Siamese bracket as –

a) Band cemented slightly off centre: tying of any one bracket.

b) One bracket can be filled with elastic or squashed.

c) Reciprocal ties

d) Lingual cleats for counter movement.

RICKETT'S TRIPLE CONTROL BIOPROGRESSIVE PRESCRIPTION[11]:

Tooth		Angulation (Tip)	Inclination (Torque)
Maxillary			
Central incisor		0^0	22^0
Lateral incisor		8^0	14^0
Canine		5^0	7^0
First premolar		0^0	0^0
Second premolar		0^0	0^0
First molar		0^0	0^0
Second molar		0^0	0^0
Mandibular			
Central incisor		0^0	0^0
Lateral incisor		0^0	0^0
Canine		5^0	7^0
First premolar		0^0	0^0
Second premolar		0^0	14^0
First molar		5^0	22^0
Second molar		5^0	22^0

FOR AUTHOR USE ONLY

SHORTCOMINGS OF THE STANDARD EDGEWISE APPLIANCE

- Too many wire bendings required to produce desired tooth movement. This made the job of the orthodontist tedious and increased the chairside time.
- Treatment priorities and results of a given orthodontist do not share characteristic features observed in other orthodontists' results. (Non-similar end results).
- The articulation of occlusal surface often did not match the classic textbook description, thus cases were under treated, in the sense that molars were not in true class I relation and incisors lacked torque.
- The long axis of the teeth on either side of the extraction site were often not parallel and also the teeth were rotated.
- The range of crown inclination and angulation of any tooth type varied considerably from one clinician to another.
- Dental casts were not mounted on an articulator to assess functional occlusal requirements.

FOR AUTHOR USE ONLY

EVOLUTION OF THE STRAIGHT WIRE CONCEPT

The title 'Straight-wire concept' was developed purposely to emphasize the term concept. The concept or idea to be developed is that a more consistent, more ideal result can be obtained with less physical and mental drain on the operator, in less over-all treatment time, and with less discomfort to the patient, with the use of an appliance which places the primary source of tooth control within the attachment rather than in the archwire.

Another attribute of this concept is the simplicity involved. It has been said- *"In art-in all things, the supreme excellence is simplicity"*.

FOR AUTHOR USE ONLY

Transition from the Standard Edgewise to the Preadjusted Edgewise system

"The birth of a new concept is never an all or none phenomenon. It is a slow evolution, with contributions from many. A new principle is an inexhaustible source of new views"

Various efforts were made to alter the design & positioning of the standard edgewise in order to reduce the necessity for wire bending.

- In 1927 Angle suggested angulating the entire bracket on the band in order to reduce the necessity for second order bends[12].
- In 1952 Reed Holdaway suggested bracket overangulation on either side of an extraction site, to reduce the second-order wire bends otherwise needed to promote both translation and angulation overcorrection[13].

- In 1957 Jarabak incorporated slot inclination to reduce the need for third-order archwire bends, so he is credited for being the first to actually build guidance into the bracket. Jarabak also recommended bracket angulation[14].
- Another attempt was made by Ivan Lee by milling torque in to the face of the bracket slot, of upper and lower incisors.
- In 1958 John J. Stiffer developed an edgewise appliance with male/female component. The female part was attached to the tooth; it was designed to receive one of many interchangeable male components with various combinations of inclination, angulations and prominence.

This was the first edgewise bracket designed to build guidance into all three plane of space. He was granted US patent for it.

- In 1960 Joseph Jarabak and Fizzell demonstrated a modified edgewise technique which incorporated 2nd and 3rd order mechanics (tip and torque) in the appliance and called it 'building treatment into the appliance'

FOR AUTHOR USE ONLY

Thus, right after the introduction of edgewise appliance in orthodontics, people started thinking about ways to achieve high quality results with lesser wire bending and simplified mechanics.

However it was only in 1970 that the first fully programmed appliance was introduced in the field of Orthodontics by Dr. Lawrence F. Andrews.

The genesis of the straight wire appliance was not a result of a single stray discovery, but rather the result of numerous experiments. Many individual innovations were distilled and combined to form this intricate design.

The concept of fully programmed appliance was evolved from a series of five studies carried out between 1960-1970 by Lawrence Andrews and his associates.

ANDREW'S STUDIES

The concept that an edgewise appliance can be fully programmed evolved from a series of five studies.

FOR AUTHOR USE ONLY

First study

It began in 1960. It involved examination of post treatment dental casts to assess the static occlusion.

By analyzing hundreds of post treatment cast in early 1960's following observations were made.

1. The articulation of occlusal surfaces often did not match the classic textbook description.
2. The long axes of teeth on either side of extraction sites were not always parallel.
3. Crown inclination and angulation varied considerably from one clinician to another.
4. Permanent second molars were routinely not included in treatment.

5. Interdental spaces (at extraction sites and other locations) occurred frequently and often seemed to result from incomplete treatment rather than from mesio-distal crown size discrepancies.
6. Teeth requiring translation were often rotated.
7. Functional occlusion was not accessed by mounting dental casts on articulator at the end of treatment, nor were intraoral photographs used.
8. There was no standardization as to whether the dental casts were registered in centric relation or centric occlusion.

Conclusion: -

This initial attempt to assess the study of art of orthodontics in terms of post-treatment static occlusion did not yield the consistent and adequate data required for firm conclusions. One implication, was clear: the paragon positions of natural teeth could be found by studying dentitions with naturally optimal occlusion.

FOR AUTHOR USE ONLY

Second study[15]*:* -

On the hypotheses that naturally occurring optimal occlusion would be worthy of emulation, casts of such dentitions were collected over a 4-year period. By 1964 the sample comprised of 120 casts.

These dentitions presented the following common characteristics: -

1. They had never been subjected to orthodontic treatment.
2. The dentitions were well aligned and pleasing in appearance.
3. They appeared to have excellent occlusion.
4. They would not benefit from orthodontic treatment.

Third study[15]*: -*

The third and- in retrospect- the most important study that led to the development of straight wire appliance (SWA) was the discovery of the six characteristics that were consistently present in the collection of 120 casts of naturally optimal occlusion. These qualities were referred to as the *Six keys to Optimal Occlusion* and they are important because:

- They are a complete set of indicators of optimal occlusion.
- They can be judged from tangible landmarks.
- They can be judged from the facial and occlusal surfaces of the crowns.

Some of the terms which are necessary in the discussion of the six keys:

Andrew's plane: The surface or plane on which the midtransverse plane of every crown in an arch will fall when the teeth are optimally positioned.

FOR AUTHOR USE ONLY

Clinical crown : The amount of crown visible in late mixed dentitions and adult dentitions with gingiva that is healthy and not recessed. However, Orban has defined the clinical crown as the anatomical crown height minus 1.8 mm.

Crown Angulation: The angle formed by the facial axis of the clinical crown (FACC) and a line perpendicular to the occlusal plane.

Crown angulation is considered positive if the occlusal portion of the FACC is mesial to the gingival portion, negative when distal.

Crown Inclination: The angle between a line perpendicular to the occlusal plane and a line that is parallel and tangent to the FACC at its midpoint (FA point). Crown inclination is determined from the mesial or distal perspective.

Crown inclination is considered positive if the occlusal portion of the crown, tangent line, or FACC is facial to its gingival portion, negative if lingual.

Embrasure line: An imaginary line at the crown's mid-transverse plane, that would connect the most facial portions of the contact areas of a single crown, or of all crowns in an arch when they are optimally positioned.

Facial axis of the clininal crown (FACC): For all teeth except molars , the most prominent portion of the central lobe on each crown's facial surface, for molars, the buccal groove that separates the two large facial cusps.

FOR AUTHOR USE ONLY

Facial-axis point (FA point): The point on the facial axis that separates the gingival half of the clinical crown from the occlusal half.

ANDREWS SIX KEYS TO OPTIMAL OCCLUSION

Key I: Interarch Relationships

This key consists of seven parts.

1) The mesiobuccal cusp of the permanent maxillary first molar occludes in the groove between the mesial and middle buccal cusps of the permanent mandibular first molar, as explained by Angle.
2) The distal marginal ridge of the maxillary first molar occludes with the mesial marginal ridge of the mandibular second molar.

3) The mesiolingual cusp of the maxillary first molar occludes in the central fossa of the mandibular first molar.
4) The buccal cusps of the maxillary premolars have a cusp-embrasure relationship with mandibular premolars.
5) The lingual cusps of the maxillary premolars have a cusp-fossa relationship with mandibular premolars.
6) The maxillary canine has a cusp-embrasure relationship with the mandibular canine and first premolar. The tip of its cusp is slightly mesial to the embrasure.
7) The maxillary incisors overlap the mandibular incisors, and the midline of arches match.

FOR AUTHOR USE ONLY

Key II: Crown Angulation, the mesiodistal "tip"

If viewed from labial/buccal aspect all crowns have positive angulations, i.e. the gingival portion of the long axis of the crown is distal to the occlusal portion.

Note: - All crowns of each tooth type are similar in the amount of angulation.

Key III: Crown Inclination, the labiolingual or bucco-lingual "torque"

Maxillary Arch:

- Most maxillary incisors (81.5%) have positive inclinations.
- Maxillary canine and premolars have negative and quite similar inclination.

- Maxillary first and second molars have negative and similar inclination but slightly more negative than those of the canine and premolars.

Mandibular Arch:

- Inclinations of the mandibular crowns are progressively more negative from incisors through the second molars.

Key IV: Rotations

The fourth key to optimal occlusion is an absence of tooth rotations.

If rotated, a molar or bicuspid occupies more space than normally— a condition unreceptive to normal occlusion. A rotated incisor can occupy less space than normal.

Key V: Tight contact

Contact points should abut unless a discrepancy exists in the mesiodistal crown diameter.

Key VI: Curve of Spee

A flat occlusal plane should be a treatment goal. Measured from the most prominent-cusp of the lower second molar to the lower central incisor, no curve was deeper than 1.5 mm in the nonorthodontic normals.

Discussion:

- Although the 120 dentitions with naturally occurring optimal occlusion show individual differences in arch form and teeth size, they generally possessed the six keys described above.
- The six keys are interdependent elements of the structural system of optimal occlusion and serve as basis for evaluating occlusion.

FOR AUTHOR USE ONLY

- The six keys can be used as treatment objectives for most patients.
- To achieve these goals may not be feasible in all instances, but to stop short when they are attainable is unacceptable.

Fourth Study[15]*: -*

It includes thousands of measurements of the crowns of the 120-cast sample. The purpose was to learn the extent to which the position, and in certain ways shape were constant within each tooth type, and how relative size was consistent within an arch.

MEASUREMENTS MADE IN THE STUDY:

- The bracket area of each tooth type
- Vertical crown contour
- Crown angulation
- Crown inclination
- Maxillary molar offset
- Horizontal crown contour
- Facial prominence of each crown
- Depth of the curve of spee

FOR AUTHOR USE ONLY

FINDINGS OF THE STUDY:

Teeth	Prominence	Angulation	Inclination
Maxillary			
Central incisor	2.1 mm	5^0	$+7^0$
Lateral incisor	1.65 mm	9^0	$+3^0$

Canine	2.5 mm	11^0	-7^0
First premolar	2.4 mm	2^0	-7^0
Second premolar	2.5 mm	2^0	-7^0
First molar	2.9 mm	5^0	-9^0
Second molar	2.9 mm	5^0	-9^0
Mandibular			
Central incisor	1.2 mm	2^0	-1^0
Lateral incisor	1.2 mm	2^0	-1^0
Canine	1.9 mm	5^0	-11^0
First premolar	2.35 mm	2^0	-17^0
Second premolar	2.35 mm	2^0	-22^0
First molar	2.5 mm	2^0	-30^0
Second molar	2.5 mm	2^0	-35^0

FOR AUTHOR USE ONLY

VARIOUS DIMENSIONS OF THE MAXILLARY TEETH:

- Offsets in molars: -

The facial cusps of maxillary molars are not of equal prominence. The mesiobuccal cusp is more prominent than the distobuccal cusp. The angle between the measuring wire and embrasure line is the offset angle. Hence 10 degree of offset is given in maxillary molar bracket (buccal tube).

VARIOUS DIMENSIONS OF THE MANDIBULAR TEETH:

No offset is needed for mandibular molars because the middle and mesiobuccal cusps are equally prominent.

Conclusions:

This study revealed consistencies of position (except for incisor inclination), morphology and relative facial prominence for the crowns of each tooth type within an arch. The differences in the incisor inclination were attributable to interjaw disharmony. Thus, special considerations must be given in bracket design correlating the inclination of incisors with the interjaw relationships.

FOR AUTHOR USE ONLY

Fifth study[15]*: –*

After evaluating the six keys to optimal occlusion and the measurements of the teeth in all dimensions, the next study began in mid 1960's and continued for a period of 10 years. In this study, 1150 post treatment dental casts displayed at the meetings of American Association of Orthodontics, Tweed foundation and the Angle society were compared with those in the untreated optimal sample, on the basis of the six keys of optimal occlusion. This study established the need for a fully-programmed appliance.

Following Conclusions were made[15]: -

Key I

Although majority of end results satisfied Angle's class I interarch relationship, however in 80% of them the true tripodal relation given by Andrews were lacking.

- In most of the cases the distal marginal ridge of the maxillary first molar did not occlude with mesial marginal ridge of second mandibular molar.
- The premolars and canines did not have a cusp- embrasure relationship.
- **Key II**

91% of the post treatment casts had one or more teeth whose angulation was different from those of the optimal sample.

- The maxillary lateral incisor and canine angulations were frequently negative, in contrast to the positive angulation in the optimal sample.
- Maxillary molar angulation often was negative or insufficiently positive in non-extraction treatment and excessively positive in extraction treatment.

FOR AUTHOR USE ONLY

Key III

- The interincisal FACC Angle was more than 180^0 in 78% of post treatment casts and less than 180^0 in 81.5% of optimal samples.
- The maxillary posterior crown inclination was not always negative in post treatment casts, as it was in the optimal sample.

Key IV

In 67% of post treatment casts rotations were evident. Most of the rotated teeth were those that had required translation during treatment.

Key V

In 43% of cases one or more spaces were present due to incomplete treatment rather than due to tooth size discrepancy.

Key VI

A curve of Spee greater than 2.5 mm was present in 56% of the post treatment casts.

Conclusions:

1. Few of the post treatment results meet the Six Key standards.
2. Treatment priorities and results of a given orthodontist share
3. characteristic features not always observed in the results of other orthodontists.
4. During the 10-year span of the formal study no discernible improvement was observed in the presence of the Six Keys.

FOR AUTHOR USE ONLY

Thus the need for an improved edgewise appliance was better understood when Angle's edgewise bracket design was examined in the light of the new information gathered from above studies about tooth shape and position, and from the new treatment goals concerning facial esthetics, which may require extractions and jaw surgery.

EDGEWISE APPLIANCE CLASSIFICATION

The several types of edge wise appliances are best differentiated by placing them into three categories[15]:

1. Non-programmed.
2. Partly-programmed.
3. Fully-programmed.

DEFINITIONS:

Non-programmed appliance :

A set of brackets designed the same for all tooth types, relying totally on wire bending (except possibly for angulation if the bracket is angulated) to achieve the optimal position for each individual tooth.

Partly programmed appliance :

A set of bracket designed with some built in features, but that always requires some wire bending (though less than in required by non-programmed appliance).

Fully programmed appliance :

A set of brackets designed to guide teeth directly to their goal positions with unbent arch wires.

THE NONPROGRAMMED EDGEWISE APPLIANCE

TERMINOLOGIES

- Angulated slot: A slot angled more or less than 90° to the bracket's vertical components.

FOR AUTHOR USE ONLY

- Bracket base: The portion of the bracket stem intented to mate with the surface of the crown.
- Bracket stem: The portion of the bracket that includes the bracket base, the lingual half of the slot, and the portions between.
- Base point: The middle of the bracket base. It falls on an extension of the faciolingal axis of the bracket stem.
- Bracket siting: Any procedure that affects positioning the bracket. Bracket siting is influenced by bracket design and crown landmarks.
- Slot base: The surface of the slot closest to the tooth.
- Slot point: The midpoint of the slot and of the (buccolingual) slot axis.
- Slot Axis: The buccolingual (or labiolingual) centerline of the slot. It is equidistant from the gingival and occlusal slot walls and is centered mesiodistally. Extended lingually, the slot axis would include the base point and the FA-point; and it would be included by a labial or buccal extension of the Andrews plane.
- Slot siting: Any procedure that affects positioning the bracket slot. Slot positioning is influenced by bracket design, bracket siting and crown morphology.
- Horizontal bracket components: The occlusal and gingival sides of the bracket.
- Vertical bracket components: The mesial and distal sides of the bracket and the wings.

FOR AUTHOR USE ONLY

DESIGN SHORTCOMINGS OF THE NONPROGRAMMED APPLAINCE[15]:

The Angle-designed edgewise brackets are “nonprogrammed” because of their bilaterally symmetrical design. For tooth movement not involving translation, six factors cause the slot of the brackets to be sited in ways that always require archwire bends. Each factor may cause the slot to be misdirected by more than 2° from its optimal angulation and inclination and by more than 0.5 mm occlusogingivally, mesiodistally, and faciolingually.

The six factors are:

1. Bracket bases are perpendicular to the bracket stems.
2. Bracket bases are not contoured occlusogingivally.
3. Slots are not angulated
4. Bracket stems are of equal faciolingual thickness.
5. Maxillary molar offset is not built in.
6. Bracket sitting techniques are unsatisfactory.

FOR AUTHOR USE ONLY

1. PERPENDICULAR BASES:

The base of the nonprogrammed bracket is perpendicular to the faciolingual axis of its stem. This feature causes problems of slot inclination and occlusogingival position.

Each crown in an arch has its own optimal amount of inclination. Therefore, brackets having bases that are perpendicular to their stems, and sited base-point to FA-point of each crown, will target their slots to that many different inclinations and occlusogingival levels.

2. BASES NOT CONTOURED OCCLUSOGINGIVALLY:

Occlusogingivally, the bracket base is flat, but the facial surface of a crown is curved.

When such a bracket is being attached to a crown, either directly or with a band, it can unintentionally be rocked occlusally or gingivally . Not only is *torque* affected by any *rolling* motion during bracket placement. So is the *height* of the slot in relation to the occlusal plane or Andrews plane, destroying proper relationships between the LA-point and the slot axis. And third, the various positions involve the *distance* of the slot from the tooth's surface, affecting in/out requirements.

(A) Rolling potential of a flat-base bracket on curved surface of a crown, indicating effects on torque, on height of slot, and on horizontal distance of slot from intended bracket site- which affects in/out requirements.
(B) Three of the possible bracket positions inherent in the rolling potential described above

FOR AUTHOR USE ONLY

Effect on torque of flat-base bracket's rolling potential.

MESIODISTAL BASE CONTOUR

The mesiodistal contour of the bracket base also does not match with that of the crown.

3. SLOTS ARE NOT ANGULATED[18]:

The slots of the nonprogrammed bracket are not angulated as per the optimal crown angulation of each tooth type thus second order bends are needed to achieve the optimal crown angulation.

- To reduce or eliminate the need for second-order bends for angulation, many orthodontists recommended angulating the brackets.
- The nonprogrammed bracket, however, was not designed for such a technique, because its base curves only horizontally.
- If any existing bracket with a horizontally curved base is angulated on the tooth to achieve tip, this creates a two-point contact between tooth and two diagonally-opposite corners of the bracket base, resulting in a potential for *rocking.*
- Under these conditions, the inclination and occlusogingival ranges for slot siting are greater than when the bracket is not angulated.

FOR AUTHOR USE ONLY

(A) When tip is built into the slot, the bracket can mate solidly with the tooth.

(B) When bracket is angulated on tooth to accomplish tip, a rocking potential is created.

4. STEMS OF EQUAL PROMINENCE[18]:

The distance from the bracket base to the center of the slot is the same in each bracket. Therefore the slots are as irregular in facial prominence as are the crowns when the teeth are optimally positioned.

5. MAXILLARY MOLAR OFFSET NOT BUILT-IN:

- The mesiobuccal cusp of each optimally positioned maxillary molar is more facially prominent than the distobuccal cusp.
- This causes the midsagittal plane of the stem and the slot to be angular to the midsagittal planes of the crown with a resultant rotational effect on the molar.
- This feature has to be corrected by incorporating first-order offset bends in the archwire.

6. UNSATISFACTORY LANDMARKS FOR BRACKET SITING:

The five traditionally used landmarks are:

- Long axis of the crown
- Long axis of the tooth
- Incisal edges and cusp tips
- Marginal ridges
- Contact points

FOR AUTHOR USE ONLY

These landmarks used traditionally for siting the bracket are unreliable and have their own deficiencies and no two orthodontist seldom agree about which landmarks are best for bracket siting.

Thus there was a need of an appliance whose design and siting system will reduce or eliminate the need for wire bending and it will also stimulate greater emphasis on diagnosis, treatment planning, and execution of treatment.

FULLY PROGRAMMED STANDARD BRACKETS

The simplest version of a fully programmed appliance consists of brackets designed to guide teeth that do not require translation. These brackets are referred to as standard brackets. There is one standard bracket for each tooth type except for the incisors and maxillary molars: for incisors there are three, for maxillary molars there are two.

To understand the design of fully programmed standard brackets, the following terminologies are required[15]:

- Auxiliary feature: A design feature that contributes to the biological aspect of treatment but is not involved in targeting the slot.
- Convenience feature: A design feature that facilitates use by the orthodontist or promotes comfort for the patient but does not contribute to the biological aspects of treatment or to targeting the slot.
- Inclined base: A bracket base that is angled more or less than 90° to the midtransverse plane of the bracket stem.
- Inclined slot: A slot whose midtransverse plane is inclined relative to the midtransverse plane of the bracket stem.
- Midfrontal plane of the crown: The plane that separates the facial from the lingual half of a clinical crown.
- Midsagittal plane of the crown: The plane that separates the mesial and distal portions of a crown at its facial axis.
- Midtransverse plane of the crown: The plane that separates the occlusal portion of a clinical crown from its gingival portion.
- Prominence plane of the crown: A plane that is at right angles to each crown's midtransverse and midsagittal planes and is 1mm farther

FOR AUTHOR USE ONLY

facially from each crown's embrasure line than is the most facially prominent cusp of the first molar in that arch.

- Slot-target point: The midpoint of the slot site for a tooth type. It is located at the junction of the crown's prominence plane and facial extensions of the crown's midsagittal and midtransverse planes.
- Slot site: The area that the slot must occupy if it is to passively receive an unbent archwire when the teeth are optimally positioned.
- Mesiodistal base contour: The horizontal contour of the bracket's base.
- Occlusogingival base contour: The vertical contour of the bracket's base.

FOR AUTHOR USE ONLY

DESIGN FEATURES OF THE FULLY PROGRAMMED APPLIANCE[15]:

The design of fully programmed brackets emanates from the slot site. The features of standard brackets include:

- Slot siting features
- Convenience features
- Auxiliary features

A. SLOT SITING FEATURES[15]:

The eight slot siting features are explained from the perspectives of the planes of individual teeth and brackets.

a) Mid-transverse plane
b) Mid-sagittal Plane
c) Mid-Frontal Plane

I. MIDTRANSVERSE PLANE[15]:

The midtransverse plane of the slot must coincide with a facial extension of the crowns midtransverse plane. To achieve this objective, the following 3 siting features are required:

Feature 1:The mid transverse planes of the slot, stem, and crown must be the same.

Feature 2: The base of the bracket for each tooth type must have the same inclination as the facial plane of the crown at the (FA) point.

Feature 3: Each bracket's inclined base must be contoured occlusogingivally to match the curvature of the crown. This feature eliminates the potential for the many slot siting variations inherent in brackets whose bases are occlusogingivally flat.

FOR AUTHOR USE ONLY

ADVANTAGES:

These three features eliminate the need for:

- Second order bends to deal with occlusogingival disharmony in slot siting.
- Third order bends for inclination.
- Other bends to deal with the inherent side-effects of wire bending.

II. MIDSAGITTAL PLANE[15]:

The midsagittal plane of each slot must superimpose on a facial extension of the crown's midsagittal plane. To achieve this objective, the following 4 features are required:

Feature 4: The mid sagittal plane of the slot, stem and crown must be the same.

Feature 5: The plane of the bracket base at its base point must be identical to the facial plane of the crown at the FA point. In maxillary molars the angle is 100^0 because of unequal facial prominence of molar buccal cusps. In all crowns other than the maxillary molars, this plane bears 90° to the midsagittal plane.

Feature 6: The base of each bracket must be contoured to match the mesiodistal radius of the area of the crown it is designed to fit. This prevents any play between the base and the crown that might cause the mid sagittal plane of the bracket to be directed mesially or distally to the crown's mid sagittal plane.

FOR AUTHOR USE ONLY

Feature 7: In each fully programmed bracket:

- The vertical components (mesial and distal borders of the bracket stem and tie wings) are designed to parallel one another. These components, when the parallel-and-midpoint bracket-siting technique is used, are to parallel and straddle the vertical landmark of the crown-the FACC.
- The horizontal components of the bracket (superior and inferior sides of the bracket stem) should be equidistant from the crown's gingiva and cusp tip which makes the base point of the bracket to mate with the crown's FA point.
- Thus, the slot point, base point and the FA point will be on a plane that coincides with the crown's midtransverse plane.

- The bracket slot is angular to each bracket's vertical component to the same extent that the mid transverse plane of the crown is angular to crown's FACC and the mid sagittal plane.

ADVANTAGES:

These three features eliminate the need for:

- First-order maxillary molar offset bends.
- First order bends to deal with errant mesiodistal slot sitting.
- Second-order bends for angulations, errant occluso-gingival slot siting caused by bracket design and by angulated brackets.
- It eliminates the side effects related to these wire bends.

III. MIDFRONTAL PLANE[15]:

The midfrontal plane of each slot must superimpose on its crown's prominence plane. To achieve this objective, the following feature is required:

FOR AUTHOR USE ONLY

Feature 8: Within an arch, all slot points must have the same distance between them and the crowns embrassure line.

ADVANTAGES:

This feature eliminates the need for first-order wire bends to accommodate for varying crown prominence.

B. CONVENIENCE FEATURES[15]:

These features make the appliance easier for the orthodontist to use and sometimes more comfortable for the patient.

Some of the convenience features incorporated are as follows: -

i. The gingival tie wings on posterior brackets are designed to extend farther laterally than they do on nonprogrammed brackets. This eliminates gingival impingement and also facilitates ligation of arch wire to the bracket.

ii. The bases of fully programmed brackets are inclined, so on mandibular molars and premolars the stem and tie wings are directed more gingivally than in the nonprogrammed brackets. This feature eliminates or reduces the occlusal interference.

iii. The facial surfaces of incisor and canine brackets are designed to parallel their bases, which in turn parallel the crown's faces. This feature is for lip comfort. For the mandibular canine it also reduces the potential for occlusal interference with opposing teeth. The occlusal tie wings of mandibular incisors are designed with the least amount of occluso-facial prominence to reduce the potential for occlusal interference with the opposing incisors.

FOR AUTHOR USE ONLY

iv. There is a convenience feature incorporated for easy bracket identification:

- Fully programmed brackets are as different as are tooth types.
- Since the brackets are smaller than teeth, their differences are not readily visible without special marking.
- Thus brackets are often marked by dots, dashes, numbers for easy identification.
- These markings enables one to identify the bracket as to:

- Which arch it is for
- Which quadrant
- Which class
- Which type
- Whether it is standard or translation bracket
- For incisors the category of inclination
- For maxillary molars whether it is for Class I or ClassII relationship.

C. AUXILIARY FEATURES[15]:

These features contribute to the biologic aspect of treatment .These are power arms, hooks, face bow tubes, utility tubes and rotation wings. Casting permits these features to be integral parts of the bracket rather than separate elements that must be added later.

FOR AUTHOR USE ONLY

INCISOR BRACKETS[15]:

- The inclination range for the incisors is greater than for any other teeth. This presumably does not reflect differing tooth morphology, but differing skeletal patterns that exist even in patients with exemplary occlusion.
- There must be atleast three standard brackets, each with a different base inclination to accommodate one of the three acceptable but different posttreatment interjaw relationships.
- To some extent, orthodontists can predict the posttreatment interjaw relationship for any patient. The base inclination for incisor brackets

selected at the beginning of treatment should conform to the crown inclinations that are harmonious with the anticipated interjaw relationship.

- As shown by *Steiner* the inclination (torque) requirement of incisors is directly related to ANB angle. Therefore proper incisor torque can be determined at the beginning of the treatment. Therefore SWA has three sets of incisor brackets designated as A, S, and C.

  Set A - for ANB Angle more than 5^0 [class II tendency]
  Set S - for ANB Angle Between 0-5^0 [class I tendency]
  Set C - for ANB Angle less than 0^0 [class III tendency]

FOR AUTHOR USE ONLY

- For maxillary central incisor, an unpublished study by Andrews (1968) of 100 cephalograms showed an average difference of 18° between the inclination of FACC and that of the the long axis of the tooth. The correct maxillary incisor bracket can be selected by subtracting 18° from the projected post-treatment inclination of the tooth's long axis relative to a line 90° to the occlusal plane.
- For class I interjaw conditions the inclination of the maxillary incisor must be approximately 25^0 ; this minus 18^0, converts to a bracket base inclinations of 7^0.
- For class III interjaw tendencies the inclination of the maxillary incisor must be 30^0, so the bracket base inclination should be 12^0.
- For class II interjaw tendencies the inclination of the maxillary incisor must be 20^0, so the bracket base inclination should be 2^0.

- In the same measurement study, the maxillary lateral incisor's inclination was found to average 4^0 less than that of the maxillary central incisor, regardless of the latter's inclination. So whatever bracket-base inclination is prescribed for the maxillary central incisor, the lateral's bracket base inclination should be 4^0 less.
- The same study indicated that the mandibular central incisor has an average difference of 16^0 between the facial axis of clinical crown (FACC) and the long axis of the tooth. The correct mandibular incisor bracket can be determined by subtracting 16^0 from the projected post treatment inclination of the tooth's long axis, relative to a line 90^0 to the occlusal plane.
- For class II interjaw tendencies the postreatment value should be approximately 20^0, so that the bracket base inclination should be 4^0.
- For class I interjaw tendencies the post treatment value should be approximately 15^0, so the bracket base inclination should be -1^0.
- For class III interjaw tendencies the post treatment value should be approximately 10^0, so the bracket base inclination should be -6^0.
- This study also indicated that the crown inclinations of the mandibular central and lateral incisors are approximately equal, so whatever inclination is prescribed for mandibular centrals would also be prescribed for laterals.
- The angulation and prominence remain the same for each incisor tooth type, for each of the 3 differing base inclinations.

FOR AUTHOR USE ONLY

POSTERIOR BRACKETS[15]:

Except for maxillary molars, only one standard bracket is needed for each tooth type. Maxillary molars require two brackets: one for class I interarch relationship and one for class II.

This is because sometimes the treatment plan calls for only first or second premolar extractions to be done in maxillary arch. In that case it is preferable to leave maxillary molars and premolars in class II molar relationship while treating rest of the dentition to class I (canine relation to class I).

Under these circumstances, the mesiobuccal cusp of maxillary molar articulates in the embrasure between the mandibular first molar and second premolar. The distobuccal cusp of the maxillary molar articulates with the mandibular molar's mesiobuccal groove, which extends farther occlusally than does the distobuccal groove.

Hence for perfect occlusal settlement, the maxillary molar should be upright rather than usual 5^0 tip present in maxillary first molar when they settle in class I molar relationship.

FOR AUTHOR USE ONLY

Thus there are two sets of maxillary molar tube: -

i. For class II molar relationship FACC of molar is kept 90^0 to occlusal plane.
ii. For class I molar relationship FACC of molar is kept approximately 5^0 to line perpendicular to occlusal plane.

FULLY PROGRAMMED TRANSLATION BRACKETS

The fully programmed standard brackets are primarily meant for non-extraction cases. If these brackets are to be used for extraction cases, then their application requires the use of first order, second order bends to carry out translation i.e. bodily movement of teeth[15].

The SWA translation brackets have built in tip, torque and in-out like standard brackets in addition to that they have a power arm and two additional slot-siting features: “counter-mesiodistal tip” and “counter-rotation”. Maxillary molar brackets include a third feature: “counterbuccolingual tip”. These features ,along with the archwire and mesial or distal force, provide countermoments for translation and the guidance needed for overcorrection in all the three planes of space. The formulae for the mesiodistal length of the brackets, length of the levers, and the amounts of countertip and counterrotation are based on moments and distances.

To understand the design of fully programmed standard brackets, the following terminologies are required[15]:

- Counterbuccolingual tip : A slot-siting feature for maxillary molars that counter acts buccolingual tip during translation and then overcorrects.
- Countermesiodistal tip : A slot-siting feature that counteracts mesial or distal tipping during translation and then overcorrects.
- Counterrotation : A slot-siting feature that counteracts rotation during translation and then overcorrects.
- Minimum translation brackets : A translation bracket for the teeth that has to be translated less than 2 mm.
- Medium translation brackets : A translation bracket for the teeth that has to be translated more than 2mm but less than 4 mm.
- Maximum translation brackets : A translation bracket for the teeth that has to be translated more than 4 mm.
- Power arm : A lever arm extending gingivally from the bracket, and used for delivering force towards the crown’s center of resistance.

FOR AUTHOR USE ONLY

- Translation bracket : A fully programmed bracket for teeth that require translation. It is designed to promote bodily movement during mesial or distal movement, and to overcorrect in proportion to the distance moved.

TRANSLATION PROBLEMS[15]:

Translation is defined as "uniform motion of a body in a straight line." For such a movement to occur, the force must be applied to the object's center of resistance. Unfortunately, a tooth's center of resistance is in its root while force is applied to the crown's labial surface through the medium of a bracket.

From the stand point of physics, a bracket located on a crown's face is in the "wrong" place in two ways:

- The bracket is occlusal to the center of resistance of the tooth, so when a mesial or distal force is applied, the tooth, instead of translating, will tend to tip around its horizontal center of rotation.
- The bracket is also located laterally to the tooth's center of resistance, so instead of translating when a mesial or distal force is applied, the tooth will tend to rotate around its vertical center of rotation.

FOR AUTHOR USE ONLY

TRANSLATION SOLUTIONS[15]:

There are two fundamental methods of moving a tooth mesially or distally, and they involve different amounts of force, bone and efficiency.

The two methods are 1) Translation

2) Tipping and angulating

Tipping & then angulating compels a portion of the root to go through the same bone twice, such a waste of energy, movement and efficiency is avoided if the tooth is translated.

LEVERS: [15]

A few principles concerning levers:

- For tooth translation, optimal lever lengths are dictated by the distance between the bracket site and the tooth's center of resistance.
- An optimal length is one in which a force of any amount capable of moving a tooth in one plane of space can be applied without causing the tooth to rotate in that plane.
- Principles concerning the potential effectiveness of levers for tooth translation are shown in the figure below.
- The edgewise bracket slot can be considered to have three levers which are present within the slot and are activated by the wire.

FOR AUTHOR USE ONLY

SLOT SITING FEATURES: [15]

Counterrotation and countermesiodistal tip are two slot-siting features common to all translation brackets. In addition maxillary molar translation brackets have counterbuccolingual tip.

The criterion for incorporating an amount of counterrotation, counter mesiodistal tip, and counter buccolingual tip is distance, because the farther the tooth needs to be translated the greater the rebound potential.

I. COUNTERROTATION: [15]

- For counterrotation the slot is rotated in the direction of translation.
- Rotation of the slot is done in one of the three specified amounts around its vertical axis.
- This feature, coupled with the flex of the arch wire, counteracts tooth rotation caused by the mesial or distal force during mesial or distal movement and overcorrects when the mesial or distal movement is complete.
- To transfer the force efficiently from the bracket slot to the centre of the crown, the mesiodistal length of the bracket should equal the distance from the slot point to the tooth's vertical axis.
- The rationale for the three increments of slot rotation is that the farther a tooth must be translated, the greater is the amount of rotation overcorrection needed.
- *The counter-rotation formulae*: --

FOR AUTHOR USE ONLY

  - 2^0 of slot rotation for teeth requiring 2mm or less of translation.
  - 4^0 of slot rotation for teeth requiring 2-4mm of translation.
  - 6^0 of slot rotation for teeth requiring more than 4mm of translation.
- Slot rotation + mesiodistal slot length + archwire flex + mesial or distal force equals counterrotation and rotation overcorrection.

II. COUNTERMESIODISTAL TIP: [15]

- The slot-siting feature for countermesiodistal tip involves rotating the slot in one of the three specified amounts around its faciolingual axis.

- The mesiodistal length of the slot is not as long as the distance from the slot point to a tooth's center of resistance.
- The countermoment produced by the angulated slot and flexed arch wire will counter act some- but not all- of the tendency for the root to lag behind the crown when a mesial or distal force is applied.
- Hence to produce pure translation, a lever as long as the distance from the slot point to a tooth's center of resistance is needed, and for every tooth this distance is greater than the mesio distal length of the slot. For example:

- Center of resistance of a typical maxillary canine is approximately 9m from the brackets slot point.
- For translation to occur, the length of the lever arm should also be 9mm.
- If the mesiodistal length of the bracket is 4mm, it will provide only 4/9 of the needed length.
- To increase the length of the lever, a gingival extensions called a power arm of 5mm is added to the bracket.
- If only the power arm is activated, the moment and counter moment will be still out of balance.
- Hence together the power arm length and the mesiodistal slot length provide the 9 mm lever needed for the counter moment to equal the moment, a condition needed for translation.

- By angulating the slot more than the standard amount provides the right amount of over angulation at the end of translation. Ultimately the tooth assumes the desired degree of angulation after rebound.

FOR AUTHOR USE ONLY

- The rationale for adding slot angulation to provide for countermesiodistal tip is the same: the farther the tooth is translated, the greater the need for angulation overcorrection.
- The amount is added to the standard amount of angulation for distal translation, or subtracted for mesial translation. *The counter-mesiodistal formulae:-*
    - Add or subtract 2° for 2 mm or less of translation.
    - Add or subtract 3^0 for more than 2mm but not more than 4 mm of translation.
    - Add or subtract 4^0 for more than 4mm of translation.
- The optimal power-arm length for each tooth type is the distance from the bracket slot point to the tooth's center of resistance, minus the mesiodistal slot length.
- The power arm for a molar bracket is shorter than that for canine because mesio-distal length of molar bracket is longer, and molar's center of resistance is more occlusal.
- The power arm for a premolar is shorter than it is for the canine because the premolar is a shorter tooth.
- The power arm extends from the gingival tie wing that is on the side of the intended direction of movement.
- In 1921 Calvin Case referred to extension soldered to bands as "power arms". Hence they are named power arms in honour of Dr. Case.
- Slot angulation + mesiodistal slot length + power arm length + activated arch wire and power arm equals countermesiodistal tip and angulation over correction.

FOR AUTHOR USE ONLY

III. COUNTERBUCCOLINGUAL TIP: [15]

- The slot-siting feature for counterbucccolingual tip involves rotating the base of the bracket in one of the three specified amounts around its mesiodistal axis.
- This feature is needed only for maxillary molar translation brackets.
- The maxillary molar is a three rooted teeth.
- When a mesially directed force is applied to a non programmed or fully programmed standard bracket, it not only predisposes this tooth to tip mesially and to rotate just like other teeth, but also tips it buccally because of the drag imposed by the tooth's dominant lingual root.
- Clinically this results in the buccal cusps becoming more gingivally oriented and the lingual cusps more occlusally positioned.
- This buccolingual tipping is resolved by the counterbuccolingual tip feature.
- This feature targets the slot to provide a more negative base inclination than would a standard bracket.
- The increased negative base inclination positions the slot so that a flat, rectangular arch wire will provide both the counterbuccolingual tip moment needed during translation, and inclination overcorrection at the end of translation stage.
- The rationale for the amount of counterbuccolingual tip is the same: the farther the tooth is translated, the greater the need for overcorrection.
- *The counter-buccolingual formulae:-*

FOR AUTHOR USE ONLY

- When the translation is to be 2mm or less, 4^0 more of negative base inclination than the standard amount.
- When the translation is to be more than 2mm but less than 4mm, 5^0 more of negative base inclination than the standard amount.
- When the translation is to be more than 4 mm, 6^0 more of negative base inclination.

➢ Base inclination + faciolingual slot length + rectangular arch wire deflection + mesial or distal force equals counterbuccolingual tip and inclination over correction.

FOR AUTHOR USE ONLY

ADVANTAGES OF THE STRAIGHT WIRE APPLIANCE[19]

1. Ease of arch wire construction. Since there is no need for bends of the arch wire other than arch form or reverse or compensating curves, bending of arch wires becomes rather simple and quick regardless of wire size.
2. No need for inter-bracket span. Since there are no bends in the arch wire, an inter-bracket span of any greater magnitude is unnecessary to reduce the force level; therefore, wide siamese brackets can be employed to control rotations.
3. Ease of arch wire placement. When the teeth are properly aligned into ideal positions, all the bracket slots lie parallel to the occlusal plane. Therefore, during leveling, the placement of the next arch wire size can be done without torquing the rectangular wire to get it to slide into

the posterior tubes. The torquing key never has to be used to place the wire into the anterior or posterior brackets.

4. Less "round-tripping." Since the teeth move in more direct vector lines from their maloccluded positions to their individualized positions, there is less "round-tripping" of the teeth.
5. Better control of tooth positions. Since all requirements for idealized tooth positions are built into the brackets rather than the arch wires, tooth positioning is better controlled and self-limiting. Missed appointments usually result in no untoward tooth movement. In fact, the actual result is improved tooth positions, which leads one to wonder whether many times arch wires are changed too soon and too often.

FOR AUTHOR USE ONLY

6. Better and more consistent results with shorter treatment time. The movement of teeth in direct vector lines to their final positions, limited by what is engineered into the appliance, results in shorter treatment time for the patient and less chair time for the orthodontist.
7. Patient comfort. Placing of large rectangular arch wires is easier for both the patient and the orthodontist with less jiggling of the teeth and therefore much less discomfort.
8. Complete space closure in both extraction and non-extraction cases can be accomplished with one set of arch wires since there are no bends in the arch wires to interfere with the brackets themselves during space closure.
9. Ease of Ligation. The gingival wings of the brackets are constructed so that they stand away from the gingiva labially and buccally.

10. Bracket Identification. Easy bracket identification due to the identifying markings that are cast into the brackets.
11. Easier, more accurate bracket placement. Specific bracket base compound curvature ensures consistent, reliable fit. Tip within bracket and torque in base permits bracket-to-crown referencig for consistent bracket placement and level slot lineup.
12. Advantage in surgical cases. The Straight-Wire Appliance offers great advantage in surgical cases where the jaw relationship discrepancy is such that occlusal forces are working against the ultimately desired tooth positions prior to surgical correction of the jaws.

FOR AUTHOR USE ONLY

DR. RONALD ROTH'S PRESCRIPTION

Over a time and through clinical testing, the values built into the original Andrews straight wire appliance were modified by Dr. Roth to what is currently known as "The Roth setup"[5]. The Roth prescription was devised in 1975 and was marketed commercially in 1976[44].

PURPOSE OF THE ROTH SETUP[5]:

- To provide idealized tooth positions prior to appliance removal that would allow the teeth in most instances to settle to what was found in the non-orthodontic normals studied by Andrews.

BASIC ASSUMPTIONS OF THE ROTH SETUP: [5]

- With appliances in place, it is virtually impossible because of bracket interference to position the teeth precisely into the occlusion shown by the non-orthodontic normal sample.

- After appliance removal, no matter how well treated the patient may be, the teeth will shift slightly from the positions they occupied at the time the appliances were removed.

Dr. Ronald Roth was using Andrews SWA since its introduction in early 1970. However after using Andrews appliance for more than 4-5 years he noted certain drawbacks in it.

DRAWBACKS OF ANDREWS APPLIANCE

1. Andrews' idea was a total concept- of which the appliance was one part- the "guidance system". Andrews' objective was to move teeth in straight-line vectors from their malpositions to their final positions by translation or bodily movement. However, the ideal force system to accomplish this has not yet been developed[6].
2. Inventory[44]:
   - In order to accomplish Andrews' goals with the force systems currently available, Dr. Andrews suggested three categories of brackets depending upon the amount (distance) of translation – *minimum, medium, maximum.*
   - Andrews later introduced different series and sets of brackets for different combinations of extractions, ANB differentials, and anchorage requirements. He developed a special classification of malocclusions and prescribed various bracket series for treatment of each, to allow translation of teeth without the need for bending offsets and also to allow for overcorrection in view of relapse tendencies[20].

FOR AUTHOR USE ONLY

- Thus if the clinician were to buy band kits for all of Andrews sets and series, it would need a very extensive as well as expensive inventory.

3. Anchorage loss[44]:

- Whenever mesially angulated brackets were placed on the posterior teeth, the teeth tend to tip mesially and migrate forward.
- The original standard Straight-Wire brackets were designed to treat only nonextraction cases with an ANB differential of less than 5° without the necessity of putting offset bends into the wire.
- However, the mesial inclination in the buccal segments creates an anchorage loss problem, especially in extraction cases.

FOR AUTHOR USE ONLY

MODIFICATIONS SUGGESTED BY ROTH:

1. Translation of teeth during orthodontics was not Roth's priority. He thought that whether an orthodontist moves a tooth by 2mm or 10mm and then fills the bracket slots with large rectangular wires and waits, the tooth eventually will attain the same position regardless of the distance it was moved. [44] He thought that the answer to this problem of extensive inventory was to come up with a prescription for a special set of overcorrection brackets that would be applicable to most cases.[20]
2. To conserve anchorage, he decided to achieve an upright position of the upper molars and premolars, and maintain the upper molars in an

overrotated position. Also the lower buccal segments are made upright and rotated distally to maintain anchorage.

3. The general overcorrection built into the Roth prescription has to do with the concept of where the teeth should be at the end of appliance therapy. According to Roth, the following factors must be considered in making the decisions regarding the amount of overcorrection.[44]
4. Overcorrection must be done very subtly so that the tooth positions will relapse to the desired positions consistently after appliance removal.
   - Overcorrection must be done because there is an angle of deflection between the largest archwire size and the bracket slot size.
   - Overcorrection must be done to compensate for the relapse of root positions that occurs after the appliance removal.
   - Overcorrection is also done because of the mechanical adversities that make it difficult to achieve proper tooth positions axially.
   - Overcorrection must be done to overcome the most common posttreatment tooth positioning errors in many cases.

FOR AUTHOR USE ONLY

ROTH PRESCRIPTION:

- In the Roth Prescription of the Andrews Appliance, the anterior brackets were placed slightly more incisally from Andrew's "middle of the clinical crown", and the ingredients of those brackets were adjusted accordingly. This was to eliminate the need to place reverse and compensating bends into the finishing wires[20].

- The Tru-Arch Form was developed to play a role in this over-correction concept, because arch form affects the rotational positioning of the teeth as well as the brackets.
- Auxiliary attachments were added to the brackets, such as double and triple tubes for headgears and lip bumpers and rectangular auxiliary tubes for Burstone or Bioprogressive mechanics.
- Additional hooks on each bracket evolved for the use of short Class II or Class III elastics, so that less unfavorable canting of the occlusal plane and less posterior interference would be created with interarch elastics.
- Placing all the four incisors at the same height overcorrects overbite and improves anterior contact during function.
- Placing bicuspid brackets 0.5 mm gingivally to the molar attatchments levels the marginal ridges.
- With open bite problems the anterior brackets may be placed more gngivally.
- In case of long clinical crowns, all brackets may be placed farther gingivally with use of a uniform increase for each that is consistent with the bracket heights listed above.

FOR AUTHOR USE ONLY

I. MAXILLARY PRESCRIPTION[20]:

- The Roth Prescription has extra torque in the maxillary incisors (5° more than normal). There is correspondingly less negative torque in the upper canines to offset the reciprocal effect of building more positive torque into the incisors.

- The upper canines have 2° more distal tip, because they are being retracted in most treatments. In addition, they have a 2° rotation to the mesial.
- There is a "Super Torque" set of maxillary anteriors to be used in the following instances:
    1. Two upper premolar extraction- only cases where a tooth size discrepancy is created (because half of a molar is smaller than an upper premolar). The additional torque and tip makes the upper anteriors occupy more space. These are used in conjuction with the zero-rotation upper molars as the mesial molar rotation created causes the molars to occupy more space in the arch. In this way the tooth size discrepancy is compensated for and proper overbite and overjet can be established and the upper extraction sites remain closed.
    2. In Class II division 2 cases and in any case that requires 6mm or more of upper anterior retraction.
- The upper buccal segments are distally uprighted to 0°, the bicuspids are rotated 2° mesially to offset the rotation that accompanies distal traction, and the upper molars have 14° distal rotation (twice the amount found on the non-orthodontic normals) and 14° buccal root torque (5° more than normal).
- There is a 0° upper molar rotation set for cases where only two upper bicuspids are extracted as explained above.
- The Zero tip canine brackets are used for segmental surgical cases to ensure space between the canines and premolars for the osteotomy cut. After healing from surgery has occurred, the

FOR AUTHOR USE ONLY

standard Roth treatment canine brackets are placed to achieve final finishing[44].

II. MANDIBULAR PRESCRIPTION[20]:

- In the mandibular arch, the incisor brackets are the same as the non-orthodontic normals.
- The lower canines have 7° mesial tip and 2° distal rotation. The entire lower buccal segment has a 3° distal tip from normal and a 4° distal rotation. These teeth settle more mesially than the uppers and simultaneously rotate mesially, thus necessitating extra distal rotation.
- The torque in the lower buccal segments remains normal, because over-correction in this plane only leads to problems and interferences.
- The two lower molars have exactly the same degree of root torque since the appliance rests on the mesiobuccal cusp (the torque measurement for the non-orthodontic normals was taken from the buccal groove).

ROTH'S PRESCRIPTION[20]

Tooth	Angulation (Tip)	Inclination (Torque)
Maxillary		
Central incisor	5^0	12^0

Lateral incisor		9^0	8^0
Canine		13^0	-2^0
First premolar		0^0	-7^0
Second premolar		0^0	-7^0
First molar		0^0	-14^0
Second molar		0^0	-14^0
Mandibular			
Central incisor		2^0	-1^0
Lateral incisor		2^0	-1^0
Canine		7^0	-11^0
First premolar		-1^0	-17^0
Second premolar		-1^0	-22^0
First molar		-1^0	-30^0
Second molar		-1^0	-30^0

FOR AUTHOR USE ONLY

- <u>According to Roth one has to accept certain Core beliefs[44]:</u>

1. Each tooth type, if reasonably normal morphologically, has identifying characteristics that make the study of dental anatomy feasible.
2. Teeth are either more curved or less curved, large or small but they are shaped similarly from one person to the next.
3. If teeth of two individuals are shaped similarly, they must occupy similar positions to fit together properly and function properly.

4. Anatomically misshapen or unidentifiable teeth will not fit properly into the arch or occlude properly with their antagonists. These teeth must be reshaped properly by the appropriate treatment.
5. Teeth belong in the alveolar process, preferably surrounded by bone and adequate gingiva.
6. The condyles should be seated in their respective fossae when the teeth meet in maximal intercuspation.
7. The anterior teeth should glide and the posterior teeth should separate on protrusive or lateral movement. This requires adequate overbite of incisors and canines (4mm) and proper overjet (2 to 3mm for incisors and 1mm for canines).
8. The face should look optimally or atleast acceptably good as a result of treatment.
9. Only minor dental compensations for skeletal discrepancy will permit a

proper occlusion; major dental compensation for skeletal discrepancies is unacceptable.

FOR AUTHOR USE ONLY

These brackets have been described as the second generation of the preadjusted brackets , Andrews brackets being the first one.

VARI-SIMPLEX DISCIPINE

The Vari-Simplex Discipline was introduced and developed by Dr. R.G. Wick Alexander. His main concern was with simplicity to encourage cooperation, comfort, and control. He believed that patient cooperation is important in any treatment, and that

complicated appliances make it more difficult for patients to succeed. Complicated systems with heavy wires, heavy elastics, auxiliaries, and complex wires and elastic placements make patient cooperation more difficult and greatly contribute to patient discomfort. One of his major goals was to make treatment easier and more convenient for the patient. That, in turn, reduces stress on the orthodontist and staff. Complicated treatment can also result in excessive treatment time for the practitioner and the patient. So, his major goals were[21]:-

- High-quality results
- Patient comfort
- Reduced chair time.

FOR AUTHOR USE ONLY

With these goals in mind, he developed an appliance called the Vari-Simplex Discipline where[21]:-

1. "Vari" refers to the variety of bracket types used.
2. "Simplex" relates to the KISS Principle (Keep It Simple, Sir). The appliance is kept simple in the following way:

- Archwire fabrication is simplified, with first-, second-, and third-order bends placed in the bracket instead of the archwire. Simpler archwires afford fewer archwire changes, and easier ligation and activation.
- Multiloop arches are rarely used because they are time-consuming, create food traps, and often impinge upon the gingival tissue.
- Hooks are rarely soldered to the archwire. Soldering is also time-consuming and can reduce archwire effectiveness. Ligature hooks are used instead, when necessary.

- All this adds up to "Simplex".

3. "Discipline" was chosen, rather than "Appliance", to reflect the idea that the orthodontist must be knowledgeable in edgewise mechanics and must play an active role in the application of the appliance to the individual patient.

CONCEPT OF THE VARI SIMPLEX DISCIPLINE: [21]

The most important factors in determining the design of the Vari-Simplex Discipline are:

1. Size and shape of the teeth, especially the mesiodistal width and curvature:-
   - These affect interbracket width, which, in turn, affects the ability to rotate the teeth and level the arch without using time-consuming vertical springs, multiloops, or extra archwires.
   - Selecting the proper bracket to fit the size and shape of each tooth will also influence ease of ligation and the ability to obtain complete bracket engagement.
2. Accessibility of the tooth and whether it is located in a curved or straight area of the arch.
3. Patient comfort
4. The frequency of bracket wing breakage.

FOR AUTHOR USE ONLY

The system evolved around five factors related to brackets: bracket selection, bracket height, bracket angulation, bracket torque, and bracket in-out.

I. BRACKET SELECTION: [21]

Each tooth has a particular bracket that is most effective.

TWIN BRACKETS: [21]

- Twin brackets (Diamond brackets) are used on large, flat-surfaced teeth— maxillary central and lateral incisors.
- The Diamond bracket is designed so that all the horizontal lines are placed parallel to the incisal edge of the tooth, and the rhomboid design makes it possible to align the vertical lines parallel to the long axis of the tooth.

Diamond twin bracket

FOR AUTHOR USE ONLY

- The flat surfaces of maxillary centrals and laterals permit full archwire engagement in the twin brackets. The accessibility of these teeth negates the usual difficulty in tying twin brackets.
- Twin brackets on the incisors allow 5-6mm of interbracket width, which is sufficient for flexibility, rotational control, and torquing ability.
- As the maxillary lateral incisors erupt, they frequently remain high relative to the normal position of the centrals, presenting a significant incisogingival interbracket discrepancy. Twin brackets on these teeth provide additional tie wings for easy initial wire placement, whereas the rotation wing of a single-width bracket might cause interference with the archwire.
- Twin brackets allow additional handles for placing power chains, ligating anterior teeth together, and placing hooks for elastics.

- A final factor is patient comfort. Twin brackets are smooth and minimize irritation of labial tissue.

LANG BRACKETS: [21]

Lang brackets were invented by Dr. Howard Lang.

- These brackets with the Diamond design are used on large, round-surfaced teeth at the corners of the arch— maxillary and mandibular cuspids.
- It is a single bracket with flat rotational control wings, each containing a circular hole. This hole increases the flexibility of the wing and could be used for ligation. Alexander design of the Lang wing has changed slightly from the original design, in using a stiffer metal for the wings, and the hole is smaller in size and closer to the base of the bracket.
- The pad is contoured so that this bracket fits beautifully on most cuspids. The straight wing of the Lang bracket eliminates interference with complete archwire engagement at this most curved position in the arch.
- The single bracket allows for easy ligation and increased interbracket width.
- The wing can easily be activated for rotational control. In extraction cases, the cuspids can be retracted on round wire with very little tipping or rotation.

LEWIS BRACKETS: [21]

- Lewis brackets are used on large, round-surfaced teeth that are not at the curve of the arch— maxillary and mandibular bicuspids— and on small, flat-surfaced teeth— mandibular incisors.

FOR AUTHOR USE ONLY

- The basic Lewis design with a wedge shape is used, which puts the tie wing close to the tooth occlusally and far out gingivally. This makes it easy to tie, to use as a hook for elastics, and to keep clean.
- The wedge shape is excellent for the application of up-and-down elastics on posterior teeth.
- The Lewis bracket is a fixed-wing single bracket, which produces sufficient interbracket width. The wings provide maximum rotational control and can be activated for additional rotation.
- The fixed wing Lewis bracket is preferred over the flexible wing Steiner bracket for the following reasons:
    1. The fixed wing is more capable of exerting additional force, especially on a rectangular wire.
    2. The fixed wing saves adjustment time, since the archwire need not be removed to activate the wing.
    3. The Lewis brackets are less sharp, so it is not necessary to tie in the archwire at the banding/bonding appointment, if, for example, we are doing indirect bonding.
    4. Breakage is not a concern when using the fixed wing Lewis bracket.
- An additional benefit offered by the single bracket with wings is that, on a tooth that is badly rotated, the wing in the direction of the rotation can be removed. The bracket can then be positioned properly, with the remaining wing serving to rotate the tooth into proper position.

Removing the interfering wing of Lewis bracket on badly rotated tooth permits proper bracket placement.

FOR AUTHOR USE ONLY

OTHER ATTACHMENTS: [21]

- Twin brackets with a convertible sheath are used on maxillary and mandibular first molars, which are usually banded.
- The convertible sheath is easily removed when second molars are banded, converting the attachment to a bracket.

II. BRACKET HEIGHT: [21]

- Bracket height is extremely important in the design of a fully activated appliance.
- Each bracket is placed at a predetermined position on each tooth relative to the other teeth.
- Bicuspid bracket height is the key factor because its clinical crown height is so variable. Its normal height is 4.5mm. It is designated as X. The other bracket heights are calculated in relation to X, as shown on the chart.

FOR AUTHOR USE ONLY

MAXILLARY ARCH

Centrals	X
Laterals	X – 0.5mm
Cuspids	X + 0.5mm
Bicuspids	X
1st Molars	X – 0.5mm
2nd Molars	X – 1.0mm

MANDIBULAR ARCH

Centrals	X – 0.5mm
Laterals	X – 0.5mm
Cuspids	X + 0.5mm
Bicuspids	X
1st Molars	X – 0.5mm

- An obvious deviation from these measurements would be in an open bite case. Since the treatment plan would be to intrude the posterior teeth and extrude the anterior teeth, the bracket height would be increased on anterior teeth by 0.5mm and decreased on posterior teeth by 0.5mm.
- It is important to position brackets in the center of the tooth mesiodistally on flat surface teeth, so that the rotating wings will be able to function properly. On bicuspids and cuspids, it is necessary to place the brackets at the crest of the contour on their buccal surfaces so that the rotating wing will be able to function optimally.

III. BRACKET ANGULATION (Tip or Second Order Bends): [21]

FOR AUTHOR USE ONLY

- The objective is to position the teeth in the most ideal axial inclinations.
- This allows the roots to be parallel to each other and the crowns to be placed in their most esthetic and functional positions.
- The Diamond bracket with angulations measured to the long axis of the crown is preferred because it simplifies bonding placement and assures accuracy.
- The horizontal incisal and gingival portions of the bracket are parallel to the incisal edge and the vertical portions are parallel to the long axis of the crown, so only the height has to be measured while bonding the bracket.
- When banding, the band is placed parallel to the incisal edge or occlusal plane of the tooth, and the bracket is angulated on the band.

- Two sets of measurements are used for angulation , depending on whether the incisal edge reference is used for banding or the long axis reference is used for bonding Diamond brackets.

IV. BRACKET TORQUE (Third Order Bends): [21]

- The pretorqued brackets for use with the Vari-Simplex discipline were introduced in 1978.
- The approach used was to measure the torques in rectangular archwires usedo finish well-treated orthodontic cases.
- The system is designed so that the best results are achieved when an .017"x .025" archwire is used to fill the .018" bracket slots.
- This leaves enough play to permit easy archwire engagement to the base of the bracket slot, which increases patient comfort.
- The rule of thumb is that .001" of play equals about 4° of torque, so each of the torques listed below should be considered to be plus or minus 4° due to play.

FOR AUTHOR USE ONLY

MAXILLARY ARCH	
Centrals	14°
Laterals	7°
Cuspids	– 3°
Bicuspids	–7°
Molars	–10°
MANDIBULAR ARCH	
Incisors	– 5°
Cuspids	– 7°
1st Bicuspids	– 11°
2nd Bicuspids	– 17°
1st Molars	– 22°

2nd Molars 0° or – 27°

These measurements differ from commonly used torques in three major respects:

- The -3° torque on maxillary cuspids— compared to extremes of + 7° to - 7° in other appliances— eliminates the need for adjusting the torque later in treatment and is enough to prevent these teeth from tipping out.
- No torque is placed in the mandibular second molar tubes as omega loops are used. As the omega is bent out to avoid impingement on gingival tissue and to create less of a food trap, the torque is automatically placed into the second molar. If the omega stop is not used, the second molar buccal tube should have the torque and the distal tip angulation built into it.
- The most important difference between the torques in this appliance and those of other appliances is that - 5° of lingual crown torque or labial root torque is built-in into the mandibular incisors brackets. This was validated in an unpublished thesis done by Dr. Dwayne Trammell as a graduate student at Baylor in 1980. This along with the rectangular wire holds the mandibular incisor in its original position.

FOR AUTHOR USE ONLY

V. BRACKET IN OUT (First Order Bends): [21]

- The appliance incorporates a system of interrelated, compensating bracket base thicknesses to replace the usual first-order bends or offsets.

CREEKMORE'S THE NEW TORQUED APPLIANCE

The New torque appliance was built by incorporating torque and other features into the brackets with the intention of building in 90% of treatment into the bracket, leaving 10% for adjustments in archwire required for individual cases. It was introduced by Thomas Creekmore in 1973[22].

FOR AUTHOR USE ONLY

BRACKET CONFIGURATION: [22]

- The basis for this technique is the Steiner Spring-Wire bracket, which is supplied with .018 and .025 channels.
- A difference between the Steiner and the Lewis brackets is in the texture of the wings. The Lewis bracket wing is rigid, whereas the Steiner Spring-Wing is flexible, which gives some flexibility from the wings in addition to the archwire.
- A modification is made in the attachment of the Steiner bracket and wing to the band. They don't weld through the wing.

- The bracket is placed over the wing and welded to the band using welds around, but not through, the wing. It has been a most important step in preventing breakage of the wings.
- The brackets are available on band strips or on preformed bands, and they can be fitted directly or indirectly.

THE LEVEL ANCHORAGE SYSTEM

The Level Anchorage system given by Terrell L. Root in 1981, is a complete orthodontic treatment system designed for those goal oriented orthodontist's who would like to treat efficiently to a predetermined goal and reach that goal on a routine basis. It is designed to quantify the anchorage requirements of the orthodontic problem and thus clarify the necessary treatment steps needed to reach the goal. The system consists of a banded or bonded edgewise appliance with built-in tip, torque, and offset and an analysis and treatment planning chart with a step-by step treatment procedure for seven different extraction and nonextraction choices[5].

APPLIANCE PHILOSOPHY: [5]

Charles Tweed was the first person to advocate anchorage preparation. He placed tip-back bends in the lower arch to vary the amount of distoaxial inclination of the lower posterior teeth. The amount of tip varied depending on the severity of the malocclusion. When this anchorage preparation was used with the standard edgewise appliance, the tip, torque and offset bends had to be placed in each edge wise arch. These bends were to be duplicated or increased in succeeding arches as the case progressed. This procedure was a challenge to even the most dedicated orthodontists.

In order to help reduce the wire bending requirement for anchorage preparation, Reed Holdaway described preangulation of the edge wise appliance in the mandibular buccal segments. He varied the angulation depending on the severity of the malocclusion. This was done based on his experiences as an instructor of the Tweed course in Tuscon. Terrell Root followed his concepts of preadjusted tip in the edgewise appliance since 1954.

FOR AUTHOR USE ONLY

Larry Andrews introduced the first completely preadjusted appliance called the Straight wire appliance. The Level A nchorage system could be described as utilizing a straight wire appliance with anchorage preparation as described by Holdaway.

PREADJUSTMENTS OF THE LEVEL ANCHORAGE SYSTEM: [5]

1. TIP:

- All the maxillary anterior teeth have a mesial crown tip:

Central incisor 4^0

Lateral incisor 7^0

Canine 6^0

- There is no tip in the maxillary premolars or first molars, but the maxillary second molars have 15^0 of distal crown tip.
- All the mandibular anterior teeth have a mesial crown tip:

Central incisor 2^0

Lateral incisor 2^0

Canine 6^0

- The mandibular 1^{st} premolar have 4^0 of distal crown tip.
- There are two choices of distal crown tip for the mandibular buccal teeth: regular and major. The choice depends on the severity of malocclusion and is determined by use of the analysis chart.

FOR AUTHOR USE ONLY

MANDIBULAR	REGULAR ANCHORAGE	MAJOR ANCHORAGE
Second premolar	4^0	6^0
First molars	6^0	10^0
Second molars	10^0	15^0

2. BRACKET AND TUBE HEIGHT: [5]

	MAXILLARY	MANDIBULAR
Central	4.5 mm	4 mm
Lateral	4 mm	4 mm
Canine	5 mm	4.5 mm
1^{st} Premolar	4 mm	4.5 mm

2nd Premolar	4 mm	5 mm
1st Molar	3.5 mm	4 mm
2nd Molar	3 mm	3 mm

3. TORQUE: [5]

ELAN AND ORTHOS SYSTEM

Elan and Orthos are two new appliance systems introduced by Craig Andreiko, that represent the first time modern CAD/CAM [computer-aided design/computer-aided manufacturing] technology has been applied to both human anatomy and appliance design in the orthodontic field[23].

ELAN:

I. APPLIANCE PHILOSOPHY: [23]

- Elan is a new dimension in treatment planning. Over the years, treatment planning and appliances have evolved to more completely address the individuality of the patient.
- Computers now aid in the cephalometric evaluation of the patient and in previewing the anticipated results. Appliances exist that are designed for extraction, nonextraction, expansion, etc.
- Elan is the first system to integrate the treatment plan and the appliance for a specific patient.

II. APPLIANCE DESIGN: [23]

- Elan begins with digitizing the skeletal and dental entity of the patient.
- The system then proceeds to design an occlusion, based on the practitioner's treatment plan and on algorithms developed to mate the three-dimensional positioning of the dentition to the skeletal framework.
- The system then designs and fabricates brackets, wires, and bracket-positioning devices that are essentially reverse-engineered from the desired final results for that individual patient.

FOR AUTHOR USE ONLY

III. STEPS IN PLANNING INDIVIDUAL TREATMENT NEEDS: [23]

- The Elan system begins with an analysis to determine the medullary center of the mandibular bone. This is converted to a mathematical equation called the Mantrough, which is the keystone of the analysis.

Development of Mantrough, with grid overlay used for selection of lingual and labial limits.

- The mandibular teeth are then placed on the curve such that the crown long axes are at specified inclinations, as opposed to the facial inclinations that have been used to date.
- The centric stops (buccal cusps) of these teeth are aligned on another smooth equation derived from Mantrough, such that the roots of the teeth are centered in the bone.
- The maxillary teeth are then placed in occlusion with the already-set mandibular teeth.
- Maxillary posterior teeth are placed with respect to centric stops and calculations for molar rotation.

- The maxillary anterior teeth are placed from calculations to provide either group function or cuspid rise parameters. Other calculations regarding tooth-size discrepancies, depth of bite, etc., are also done at this time.
- Essentially, the system does an ideal setup for each case.

FOR AUTHOR USE ONLY

III. ADVANTAGES: [23]

- It is an evolution of preadjusted appliances. Since the system can capture the "personality" of the practitioner and match this to the individual patient, it is essentially the same appliance he or she is now using, with much more of the guesswork eliminated.
- This system allows the practitioner to concentrate more on treatment planning and less on adjusting for the mismatch between the appliance and the patient.

IV. BRACKET: [23]

- TYPE: Currently, the system is available only in the twin configuration, but it has long-term plans to encompass all techniques, including ceramic and plastic appliances.
- SLOT SIZE: Both .018" and .022" slots are available currently.
- PLACEMENT: Mandibular brackets are placed as occlusally as possible for hygiene while assuring clearance from the buccal cusps of the maxillary teeth in the final occlusion. The maxillary brackets are placed fairly centrally, due to the absence of interferences.

VI. CROWN LONG AXIS: [23]

- The crown long axis, as used in the Elan system, is a line that passes through points of bisection of the incisal edge and the cervix of the tooth, as seen from a mesiodistal profile.
- The system works more off the body of the tooth, essentially, but also utilizes specific occlusal landmarks to more accurately control root positioning.

FOR AUTHOR USE ONLY

ORTHOS: [23]

Orthos is a new average prescription and appliance design based on computer
analysis of more than 100 cases derived from the Elan technology. It is a coordinated system of brackets, buccal tubes, and wires.

It contains refinements and upgraded logic from the other currentlyavailable prescriptions. The computer logic written to solve functional and static occlusal puzzles and the appliance design software

developed for Elan are being used to design the Orthos average appliances.

FACTORS AFFECTING APPLIANCE DESIGN AND PERFORMANCE: [23]

- By utilizing new rotation-in-slot technology, the lower anterior brackets have been reduced in the faciolingual dimension while, at the same time, the 1st-order relationship between lower cuspids and anteriors has been corrected.
- Mandibular posterior segments have less negative torque than prior designs to keep these teeth from being inclined lingually.
- Orthos archwire forms are taken from skeletal studies and are also "coordinated" mathematically for the first time.
- Molar rotations are calculated from actual anatomy for the first time.
- The mandibular arch has more progressive tip to aid in root paralleling.
- Mandibular bicuspids have distal root tip to level marginal ridge contacts.
- Upper second bicuspids have distal tip to level marginal ridges between the second bicuspids and the first molars, and they are thicker than the first bicuspids to reduce the need for bayonet bends.
- Upper posterior segments have more buccal root torque to keep the dangling lingual cusps from causing balancing interferences with the prominence of today's expansion mechanics.

FOR AUTHOR USE ONLY

Effect of progressive tip on root paralleling (top: typical prescription; bottom: Orthos values).

VIAZIS BIOEFFICIENT THERAPY

Bioefficient Therapy was given by Dr. Anthony Viazis. It is a patient-friendly and user-friendly system designed to shorten the time-consuming initial phase of treatment. By proceeding more quickly to an individualized finishing stage, it reduces burnout for both patient and clinician and produces noticeable results early in treatment, improving patient cooperation and the quality of care[24].

BRACKET DESIGN: [24]

Conventional single brackets have not been as popular as twin brackets because they have virtually no capability of controlling rotations or tipping. Dr. Viazis developed a multifunctional single bracket for Bioefficient Therapy that solves this design problem while providing optimal tooth movement. Its capabilities are:

FOR AUTHOR USE ONLY

1. *CONFORMITY TO CROWN ANATOMY AND GINGIVAL OUTLINE*: [24]

- This is especially useful in the case of bicuspids, where the brackets can be placed as far gingivally as needed because of a narrow, rounded gingival end.
- A low profile allows the brackets to blend in well with the archwire, and the side elbows are hidden behind the elastomeric modules after ligation.
- *EASE OF USE*: [24]Variability in bracket positioning is usually attributable to improper mesiodistal or buccolingual placement of the

slots. With the new brackets, if the operator aims the ball indicator toward the center of the curvature of the gingiva, the vertical member automatically lines up along the long axis of the tooth.

- Vertical position can be easily verified with a periodontal probe. If brackets without ball indicators are used, the vertical member can be visually aligned along the long axis of the tooth and checked with the probe.
- The side elbows help with mesiodistal orientation. Assuming the tooth is a normal shape, the incisal edge of the tooth should be parallel to the horizontal member of the bracket.
- Improper ligation of elastomeric modules can result in added staff time and patient discomfort. This bracket design makes ligation easy and secure, since both the wings and the elbows are used.

FOR AUTHOR USE ONLY

Both wings and elbows of new brackets (left) can be used for ligation. Larger interslot distance (x_1) compared to conventional twin brackets (x_2) allows much greater wire flexibility. Shorter interbracket distance increases wire stiffness for rotation control.

2. *MINIMUM FRICTION*: [24]

- The bracket slot is elevated from the horizontal member. This single-slot contact produces the least amount of wire-bracket contact and thus the lowest possible friction.

3. *TIP CONTROL*: [24]

- The main problem with conventional single brackets is loss of tip control. In the new bracket design, as soon as a tooth begins to tip (as

in space closure), the archwire contacts the side elbows, and the single slot momentarily becomes a wide twin slot that produces root movement before any further crown movement. Thus, the tooth "walks" back in a zigzag fashion.

- The interelbow distance is much shorter than the interslot distance, and therefore the wire is much stiffer between the elbows, resulting in better leveling and root parallelism.
- The tooth movement is continuous and controlled.

4. *ROTATION CONTROL:* [24]

- The narrow, elongated configuration of the brackets, with the wings moved toward the mesiodistal surfaces of the teeth, provides maximum rotation control.
- Depending on the amount of rotation control needed, either of two configurations of elastomeric modules can be used. For maximum control, the elastomer is slipped over one wing of the horizontal member; both sides of the module are then passed behind the vertical member and over the other wing.
- For a quicker rotation correction, the module is placed over the vertical member and then under the wing of the side that needs correction.With this method, the module partially covers the slot. As the archwire is placed, the module is displaced to the side, and the opposite side is tied with a steel ligature. Thus, the module acts like a Steiner wedge.

6. *VERTICAL SLOT:* [24]

- A vertical slot is a helpful bracket feature even for clinicians who do not use it consistently, because it can be used with the new nickel

FOR AUTHOR USE ONLY

titanium uprighting springs to enhance and detail tooth movement during the finishing stage. The slot does not add significantly to bracket width.

7. *HIGH ANTERIOR TORQUE*: [24]

- It is more efficient and less time-consuming to have torque built into the brackets than to torque the archwires. Because most clinicians finish with undersize wires, extra torque is needed to counteract any tipping effect produced by active mechanotherapy, especially during space closure.
- The bracket prescription for the Bioefficient system was designed to overcorrect malocclusions and to make it possible to work with the largest possible wires from the start of treatment.
- It is a modification of the preadjusted systems developed by Roth, Andrews, Alexander, and Hilgers.
- The torque-in-base brackets are diagonal in shape, and the bases have anatomically contoured triangular shapes.
- The height of the upper central incisor bracket is designed so that the middle of the tooth (the FA point of Andrews) coincides with the bracket slot. Other bracket heights are decided according to the distance of the base from the incisal edge. [24]

FOR AUTHOR USE ONLY

Bracket heights and prescriptions (x = distance from upper central incisor bracket base to incisal edge; y= distance from lower central incisor bracket base to incisal edge).

It should be emphasized that it is impossible to fit all patients into the same bracket prescription. Full-size or undersize wires should be

used as the case dictates, and individualized finishing is almost always required. [24]

BRANDT TORQUEONTROL SYSTEM

The new edgewise type bracket and arch wire selection permits tip control, sliding mechanics with straight arch wire and initial continuous programmed torque in the upper front region where it is needed most.[25]

APPLIANCE DESIGN: [25]

- The system has 0.020″ slot for the upper anterior teeth for active programmed control of bodily movement and torque of the anterior teeth.
- It uses 0.022″ slot for the buccal teeth for optimal sliding mechanics.

FOR AUTHOR USE ONLY

PRINCIPLE OF THE TORQUEONTROL SYSTEM: [25]

- Upper anterior teeth: High effective torque
- Buccal segment: Maximal sliding mechanics

RACKET POSITION: [25]

	MAXILLARY	MANDIBULAR
Central	4.5 mm	4.5 mm

FOR AUTHOR USE ONLY

DUAL ENVIRONMENT BRACKET

The Dual Environment bracket was introduced by George F Schudy in 1990.[26]

APPLIANCE PHILOSOPHY: [26]

- According to the author, the ideal edgewise bracket should offer a maximum range of action for wires, yet still permit precise control with small edgewise wires and require minimum change in technique.
- A new bracket was designed to capitalize on the computer modeling that demonstrated the advantages of small wires and greater intrabracket space, but without the disadvantages of the Bi-Metric appliance.

BRACKET CONFIGURATION: [26]

- The bracket has a large outer slot, for maximum archwire flexibility in the initial phase, and a small inner slot that accepts small rectangular wires for maximum control later in treatment.

FOR AUTHOR USE ONLY

Dual Environment bracket with large outer slot (F) and small inner slot (P).

- The outer slot measures .040" for twin brackets and .030" for single brackets.
- The inner slot can be either .016" or .018".
- The flexibility of the outer slot in some cases allows the use of a full-size .016" x .022" initial archwire, even with a great deal of irregularity.
- The inner slot is used after rotations have been partially corrected and vertical alignment has been accomplished. The same full-size wire can then be seated in the smaller slot.
- This new bracket allows the teeth to adjust comfortably during the initial phase of treatment.

- Therefore, patients experience little discomfort when the wire is seated in the inner precision slot after two to four weeks.

ADVANTAGES: [26]

- Faster leveling of arches with fewer arch changes. The large posterior intrabracket space allows less friction with working arches, permitting the teeth to move more easily both vertically and horizontally.
- Easier torquing of teeth with less discomfort. Torquing efficiency is directly proportional to the length of the wire and inversely proportional to its stiffness. For a given span, an .016" x .022" wire has 38% more deflection than an .018"´x .025" wire and 68% more deflection than an .022"x .028" wire. Seating torque of even 30-45° is virtually painless for the patient. Lighter torquing forces are also associated with reduced root resorption.
- Fewer permanent sets in archwires due to mastication. The working arch is not closely held in the posterior brackets; it flexes within the slots and acts as a shock absorber to prevent strain on the wire from chewing.
- This two-slot bracket allows the clinician to move sequentially from an appliance that increases range of action by maximizing intrabracket space and minimizing control, to one that exerts anterior and terminal molar control, to one that finally engages all the teeth with precision control. In addition to its efficiency, the appliance greatly reduces patient discomfort.

FOR AUTHOR USE ONLY

MCLAUGHLIN, BENNETT AND TREVISI SYSTEM

McLaughlin and Bennett worked with Trevisi to re-design the entire bracket system to complement their proven treatment philosophy and to overcome the perceived inadequacies of the original SWA.[27,28,29]

They re-examined Andrew's original findings, and took into account additional research input from Japanese Sources and brought about the MBT Bracket System which they called "Third generation of preadjusted appliance. "

According to various arch forms' research it was recommended to use 3 different arch forms according to different clinical situations. These were- tapered, square and ovoid. When superimposed, they vary mainly in inter-canine and inter pre-molar width, giving a range of approximately 6mm. However the inter-molar widths of the three shapes were similar.

FOR AUTHOR USE ONLY

Also they further updated light force levels by the use of heat activated Nickel- titanium wires (HANT) re-stating the overall treatment philosophy.

Following changes were made in the standard SWA Brackets: - [27,28,29]

- Original dots and dashes system for brackets identification was changed to laser numbering of standard metal brackets.

- Brackets were available in standard size metal , mid-size metal, clear forms .
- Rectangular shape was replaced by rhomboidal form to reduce the bulk of each bracket.

- Torque in base-the Computer –aided design (CAD) factor --

  Torque-in-base was an important issue with the first and second generation preadjusted brackets. Technology was not available to set bracket slots in the correct position relative to the facial surfaces of the crown without torque-in-base.

  Since the advent of CAD-CAM bracket design, the brackets may be finished with all torque-in-base (full size and clear) or a combination of torque-in-base and torque-in-face with absolutely no difference in slot position.

FOR AUTHOR USE ONLY

- Refinement of bracket base design

It is incorporated to increase the strength and help plaque control in difficult areas.

- Lower premolar bracket may be offset on specially designed base, to increase bond strength and reduce the risk of bond failure.
- Tapered bracket bases on lower incisors can help in plaque control in this difficult area.
- Change in Anterior bracket Tip Specification:

Thus, in original SWA Brackets, their was additional tip built into the anterior upper brackets by 10^{o} and lower anterior bracket by 12^{o} in total from the MBT Brackets.

Disadvantage of additional anterior tip: -

1) It creates significant drain on antero-posterior anchorage.
2) It increases the tendency for bite deepening during the alignment stage.
3) In some cases it brought the upper canine root apex too close to the first premolar root apex.

As the lighter forces were used in all stages of treatment by MBT philosophy, this additional anti-tip or second-order compensation was not necessary and so in MBT bracket system the tip of bracket was same as the original research value. This also dramatically reduced anchorage needs of each case, and put less demand on patient co-operation.

As the MBT values are based on Andrew's original research values, there is no compromise in ideal static occlusion.

And if the condyles are in centric relation, there is no compromise in ideal functional occlusion as described by Roth.

FOR AUTHOR USE ONLY

tooth	SWA Tip		Recommended Tip	
	LOWER	UPPER	LOWER	UPPER
Central Incisor	2^0	5^0	0^0	4^0
Lateral Incisor	2^0	9^0	0^0	8^0
Canine	5^0	11^0	3^0	8^0
First premolar	2^0	2^0	2^0	0^0
Second premolar	2^0	2^0	2^0	0^0

- Change in upper posterior bracket tip specification:
- Upper bicuspid brackets are provided with 0^0 tip to keep these teeth in a slightly more upright position, more in the direction of Class I, and also reduces the anchorage needs in some cases.
- Upper molar brackets are provided with 0^0 tip, which when placed parallel to the occlusal plane, introduces 5^0 tip into the upper molars.

- Change in lower posterior bracket tip specification:
- Lower posterior tip in the first and second bicuspid brackets is maintained at 2^0, to slightly incline these teeth forward.
- For the lower first and second molars, 0^0 tipped brackets are provided, which when placed parallel to the occlusal plane, introduce 2^0 of tip to these teeth.

FOR AUTHOR USE ONLY

- Torque specification:

In original standard SWA brackets the built-in torque was relatively inefficient in delivering torque. It was therefore necessary to build extra torque into the important incisor and molar region in order to meet clinical goals with minimum wire bending.

Torque is not efficiently expressed by the preadjusted appliance system owing to two reasons:

1. The area of torque application is small and depends on the twist effect of a relatively small wire compared to the size of the tooth.
2. In order to slide teeth it is normal practice to use .019/.025 steel wires in the .022 slot .These wires have a slop of about 10°

- Incisor torque specification:
- Upper incisor brackets are provided with additional palatal root torque, while lower incisor brackets are provided with additional labial root torque.
- This adjustment aids in the correction of the most common torque problems occurring in the incisor areas.

- Upper Cuspid, bicuspid and molar torque specification.
- Upper cuspid and bicuspid brackets are provided with the normal -7^0 of torque.
- Upper molar brackets are provided with an additional 5^0 of buccal root torque (-9^0 to -140) to reduce palatal cusp interferences with these teeth.
- Upper canine torque. Available in -7^0, 0^0, $+7^0$, torque.
- The 0^0 and $+7^0$ options are for cases with narrow maxillary bone form and\or prominent canine roots, and are often used with archwires in the tapered form.
- There was a tendency for upper first molar palatal cusps to extrude. Bracket with – 14^0 of buccal torque gives extra control.

In some cases it is necessary to add buccal root torque to the upper archwire, even when using a -14^0 torque bracket.

FOR AUTHOR USE ONLY

- Lower cuspid, bicuspid and molar torque
- Progressive buccal crown torque is provided in the brackets of the lower posterior segments.
- This allows for buccal uprighting of these teeth, which is beneficial in most cases.
- Also, the original SWA first molar torque -30°, second molar torque -35° allowed rolling-in of lower molars.
- Therefore the lower premolar torque was changed by 5°,first molar torque by 10° and second molar torque by 25°.
- Lower canine torque available in -6^0, 0^0, $+6^0$.
- The 0^0 and $+6^0$ options are for cases with narrow mandibular bone form or prominent canine roots, or deep bites at start of treatment.

FOR AUTHOR USE ONLY

- In-out specification

- It is 100% fully expressed because the archwire lies snugly in the slot.
- An upper second bicuspid bracket with an additional 0.5mm of in-out compensation is provided for the common situation in which upper second bicuspids are smaller than upper first bicuspids.
- This is helpful in obtaining good alignment of marginal ridges in cases with small upper second premolars.

➢ Factors, which govern the selection of canine brackets.

1. Arch form.
2. Canine prominence.
3. The extraction decision (tip control).
4. Overbite.
5. Rapid palatal expansion.
6. Agenesis of upper lateral incisors, where space is to be closed.

1. Arch form.

Well-developed arches -- -7^0 upper & -6^0 lower.

Ovoid / tapered arches -- 0^0 upper & lower.

Narrow tapered arches -- $+7^0$ upper & $+6^0$ lower.

FOR AUTHOR USE ONLY

2. Canine prominence.

In cases with prominent canine / canine with gingival recession use 0^0 torque or $+7^0$ upper & $+6^0$ lower torque.

3. The extraction decision (tip control).

In cases of premolar extraction, canine bracket having 0^0 torque are used. This is because 0^0 brackets tend to maintain the canine roots in cancellous bone, Thereby making tip control of the canine roots easier.

4. Overbite.

In many deep bite situations like for eg. In class II div. 2 case, there is often a requirement to move the canine crowns labially, but to maintain the roots centered in the bone. This is more readily achieved if 0° or +6° lower canine brackets are used.

5. Rapid palatal expansion

As rapid palatal expansion creates secondary widening in the lower arch , use of 0^0 or $+6^0$ torque brackets on lower canine tooth helps in uprighting the lower teeth to assist the favorable change.

6. Agenesis of upper lateral incisors, where space is to be closed.

If one or both the upper lateral incisors are missing, a decision may be made to close the spaces, and bring the canines in contact with the central incisors.

A +7° torque bracket may be used by inverting the -7° bracket which also maintains the tip at 8°.

FOR AUTHOR USE ONLY

- Some other modifications
- Lower Second premolar tubes:

ADVANTAGES:

- Decreased occlusal interference of the opposing teeth, mainly in overbite and class II cases.
- Comfortable to the patient.
- Decreased friction during the sliding mechanics.
- Decreased chairside time as the tubes are self-ligating.

- Lower second molar mini tubes:

Helpful in cases where the inter-occlusal space and the gingival tissue do not allow the placement of regular banded molar tubes or bondable molar tubes.

- Lower first molar non-convertible tubes

Advantages:

1. Comfortable, cleaner and stronger than Convertible tubes
2. Fewer interferences and hence accurate vertical positioning

FOR AUTHOR USE ONLY

BEGG LIGHT WIRE APPLIANCE

The Begg technique was introduced by percival Dr. Raymond Begg. Begg studied and worked with Angle from 1924-25. During that time, although Angle was still teaching the ribbon arch appliance, he was working simultaneously on a new mechanism in which he turned the ribbon arch bracket by 90^0 and inserted it "edgewise" into "tie brackets" with slots in their faces.[30]

Dr. Begg and Fred Ishii, were the first to treat patients with this new appliance. According to Begg, Angle stated openly that he changed the orientation of the bracket slots to make it easier for the "not so clever orthodontist". According to Angle, upper and lower edgewise wires can be preformed to ideal shapes prior to placement and the dental arches expanded by drawing teeth towards the archwires with ligature ties. Because Angle advocated nonextraction treatment, there were few spaces to close. He also developed the edgewise mechanism to achieve better control of the mesiodistal axial inclinations of teeth. [30]

FOR AUTHOR USE ONLY

After returning to Australia in 1925, Begg practiced the edgewise mechanism for 2 yrs and followed the nonextraction philosophy. He soon became dissatisfied with many of his post-treatment profiles and was often faced with serious relapses. [30]

Accordingly in 1928, he began, when indicated, to remove teeth and/or reduce tooth substance by stripping and recognized the role of attrition in human dentition. He realized that edgewise mechanism was not designed to rapidly close extraction spaces and reduce deep over bites. He also observed that edgewise brackets, even when used in conjunction with round archwires, could cause undesired root movements. The unavoidable uprighting of mesiodistally tipped teeth

caused by the placement of archwires in edgewise brackets created an unnecessary strain on intraoral anchorage and often resulted in anterior teeth being being bodily repositioned across the midline. To avoid these problems, Begg discarded wide-channel brackets and began using ribbon arch brackets, facing the slots gingivally rather than occlusally. A ribbon arch bracket, used in conjunction with a round archwire, permits free tipping in all directions. In 1956 he introduced the concept of differential force system. [30]

BRACKET CONFIGURATION: [30]

The Begg technique employs modified ribbon arch brackets whose flanges accept a direct bonding pad or can be spot welded to a band. The archwire slot is 0.020 x 0.045 inches to accept both a 0.020 inch arch wire and, when required, a 0.016 inch torquing auxiliary. Two vertical slots, one on either side of the archwire, accept lock pins and/or auxiliaries.

FOR AUTHOR USE ONLY

BRACKET PLACEMENT :[31]

- Brackets are centered mesiodistally on the labial or buccal surface of the teeth with the base of the arch wire slot 4 mm from the incisal edges or cusp tips.
- The only exception to this vertical placement is the maxillary lateral incisor, brackets on these teeth are set closer to the incisal edges at 3.5 mm, to automatically provide the desired esthetic shortening of these teeth in relation to their neighbours.

BASIC TENETS OF BEGG MECHANOTHERAPY:[32]

- Use of light orthodontic forces.

- Splitting of bodily movement into the crown tipping movement followed by root movement, for an efficient bodily translation with the least taxation of the anchorage.
- Use of brackets permitting free tipping movement in the initial stages due to minimum friction between the wire and bracket.
- Use of differential forces for the movements of different groups of teeth.
- A definite sequence of stages as also treatment steps.
- Use of light intra-oral elastic forces.
- En-Masse movements of anterior and posterior teeth for attaining the objectives like overjet reduction and correction of posterior occlusion.
- Separation of root moving forces from arch wire forces.
- Over correction of all the displacements.
- Use of high tensile strength round wires.

FOR AUTHOR USE ONLY

ADVANTAGES:[5]

- Light optimum force levels are used throughout the treatment, which are physiologically more acceptable and are comfortable to the patient.
- Relatively continuous force application.
- Minimal friction of wires in brackets and tubes.
- Rapid alignment, leveling and rotation of anterior teeth.
- Rapid and efficient overbite correction chiefly by means of molar extrusion and incisor intrusion.
- Simultaneous crown tipping and retraction of all anterior teeth.
- Relatively continuous paralleling of roots at extraction sites by auxiliary springs.

- Relatively continuous torquing of upper, or occasionally, lower incisors.
- Extra-oral force not necessary except with extreme anchorage problems.

DISADVANTAGES: [5]

- Difficulty in coordinating maxillary and mandibular arch form and width.
- Difficulty in obtaining bilateral symmetry.
- Difficulty in obtaining control of premolar and molar torque without the use of auxiliaries.
- Difficulty in stabilizing teeth during final artistic positioning.

FOR AUTHOR USE ONLY

MODIFICATION OF BEGG TECHNIQUE

This was introduced by Dr Akira Kameda. He modified the Begg technique to comply with the demands of time and progress of technology .

This was based on 25 yrs of clinical experience. The basic idea was to solve unfinished and/or unstable parts of pure Begg technique. He thought that the drawbacks of the technique were:[33]

- Emperical diagnosis.
- Unnecessary and over tipping teeth in mesio-distal and labio-lingual planes which includes anchor molars.
- Collapse of the arch form.
- Rotations and mesial tipping of second premolars.
- Stage III was mechanically taxing with several unfavourable side effects.
- Gummy smile with canting of the occlusal plane.

FOR AUTHOR USE ONLY

Since 1972 he has sought to rectify these deficiencies of Begg technique and this has resulted in the development of the Kamedenized Begg technique.

APPLIANCE PHILOSOPHY: [33]

- Dr. Kameda states that most malocclusions are comprised of labio-lingual alignment problems, with mesio-distal axial inclination problems consisting only a minor part.
- It is therefore, irrational to correct these problems by tipping teeth mesiodistally as is done in pure Begg technique.

- These malocclusions for correction resolution need tooth movement in the labio-lingual plane.
- The fundamental difference in the tooth movement of Kamedanized Begg technique when compared with pure Begg technique is in the direction and the magnitude of the tip.

BRACKET CONFIGURATION: [33]

- In 1983 , he introduced torquing and reverse torquing brackets.
- The classical Begg bracket configuration was retained but it had torque built into the base of the bracket.
- Built in torque adjustments is obtained by raising the incisal or gingival edge of the bracket base away from the tooth surface by using metal wedges between the base of the bracket and the bonding mesh pad.
- The amount of torque built-in was 20° for the upper incisors and -10° for the lower incisors.
- These brackets are to be used according to the specific clinical problem.
- The usual pattern of usage is as follows:

	Upper incisors	Lower incisors
1. Class II malocclusion	20°	-10°
2. Class III malocclusion	-10°	20°

- Individual teeth needing torque/reverse torque may receive appropriate brackets.

FOR AUTHOR USE ONLY

THE BEDDTIOT APPLAINCE

The appliance system known as the Begg-edgewise diagnosis-determined totally individualized orthodontic technique (BEDDTIOT) offers the capacity to employ selected principles and features of Begg and edgewise mechanisms in specific situations in which they are most advantageous.[34]

APPLIANCE PHILOSOPHY: [34]

- The appliance was developed to meet specific criteria, characteristics deemed to be most desirable in an orthodontic appliance
- . The primary goal was the facility to treat each patient's needs in the manner most efficient for that individual.
- The intent was toincorporate the important advantages, features, and capabilities of many fixed appliances and minimize deficiencies, making the most of current understanding of orthodontic biomechanics and technology.
- The control and precision of edgewise appliances (having full torque and angulation built in) is combined with the capabilities for anchorage conservation and rapid tooth movement (of the "light-wire differential force" approach to biomechanics) by means of attachments that are versatile, simple, economical, and small.
- Treatment is *individualized.*
- Begg principles are employed in some cases; various edgewise techniques in others. A wide variety of combinations may be employed easily.

FOR AUTHOR USE ONLY

BRACKET CONFIGURATION: [34]

- The brackets are narrow, single-width (0.050 inch or 1.3 mm) edgewise brackets with 0.022 inch (height) and 0.028 inch (faciolingual depth) horizontal arch wire slots.
- On the lingual side of the bracket (that is, against the band or bonding pad) is a 0.020 x 0.020 inch vertical slot.

BEDDTIOT bracket on universal bonding pad

- The arch wire slots are "torqued" (cut at such angles to the brackets that they will be oriented parallel to the plane of the arch when the teeth are positioned properly.

FOR AUTHOR USE ONLY

Cross section of the bracket with 20° lingual crown torque on Mandibular second premolar

- In average cases the appropriate brackets to assign to the various teeth will be determined by the slopes of the facial surfaces of the teeth.
- Since the slope of the surface of any particular tooth varies among patients, the operator should exercise judgment in the selection of appropriate brackets.
- Except for torque, the brackets are all identical. Therefore, they are interchangeable; any bracket may be used on any tooth.
- Placed with its torque-indicator groove gingival, a bracket provides lingual root torque; with the groove occlusal, it provides lingual crown torque.
- The standard torques make up a set with a smooth progression—0°, 5°, 10°, 15°, and 20°. Thus, an appropriate bracket is available for most situations.

TORQUE: [34]

	MAXILLARY	MANDIBULAR
Central	-10°	0°
Lateral	-5°	0°
Canine	0°	10°
1st Premolar	5°	15°
2nd Premolar	5°	20°
1st Molar	10°	25°

FOR AUTHOR USE ONLY

- Each of the five brackets prewelded on both flat and curved universal bonding pads provides maximum versatility. The pads are of minimal size, and their shape facilitates the placement of the brackets with either end toward the gingiva. In this way each may be used for either lingual crown or root torque.
- The brackets are milled from solid bars of stainless steel.
- They have arch wire slots that open on the facial surface; thus, malpositioned teeth are usually moved directly toward engagement with the arch wire because full advantage can be taken of the resilience of both the arch wires and elastomeric ligatures.
- Alignment can be achieved with the use of long-range, low-magnitude forces.
- The brackets are small in all dimensions to ensure optimal appearance and minimal lip and cheek irritation. This also lessens occlusal interference, enamel surface involved in bonding, and problems with gingival proximity and oral hygiene.

- Narrow brackets have long, resilient spans of arch wire between them— a great advantage over twin bracket edgewise. A wire in narrow single brackets has approximately twice the elastic range of the same wire in twin brackets and is only about one half as stiff, that is, produces only one half as much force in a given deflection.
- The fact that a wire is distorted less in the engagement of narrow brackets magnifies their advantage; less elastic range is required and less force is produced.
- The dimensions of the arch wire slot allow considerable (but limited) mesiodistal tipping on undersized wires (10° distal crown tip on 0.016 inch, the usual working wire), as well as limited uprighting (5° mesial crown tip on 0.018-inch arch wire).
- Uprighting springs may be inserted in the 0.020 x 0.020 inch vertical slot. Uprighting springs are not needed for "braking" (to prevent overtipping) and need not be removed before treatment is truly completed (they cannot go too far).
- The vertical slot has many potential uses. It can accommodate ligatures, elastic hooks, rotation devices, and various other auxiliaries. Turned 90° (so it is horizontal), it can serve as a miniature buccal tube. An example of its function as a buccal tube would be to gain control of partially erupted or impacted second molars that require uprighting or crossbite correction.

FOR AUTHOR USE ONLY

TIPEDGE

In the past, the ribbon arch bracket used by Dr. P.R. Begg in the Begg technique provided the freedom required for rapid tooth movement from relatively light forces. But however, Begg died in 1983 still searching for a way to achieve final, positive, three-dimensional control from a ribbon arch-type bracket. But he never looked at the edgewise bracket as the solution, since he always considered it the problem.[44]

The edgewise mechanism with conventional, static archwire slots was the most popular appliance during that period. But even this appliance had deficiencies like there are no provisions in the edgewise archwire slot to facilitate anteroposterior interarch corrections, for anterior bite opening and for opening or closing spaces. Subsequent changes had also been made in the edgewise appliance, since its invention by Angle such as wider, twin brackets and preadjusted arch wire slots, which have increased and refined the level of tooth control. Yet, these modifications made it more difficult to accomplish the major repositioning of both teeth and the jaws that is often required. [44]

FOR AUTHOR USE ONLY

In 1986, a change in the design of the arch wire slot made by Dr. P.C. Kesling, corrected all these problems. The modification was the removal of diagonally opposed corners from the conventional edgewise slot to permit either mesial or distal crown tipping. [44]

Such modification of the slot could not have been considered by Angle, because at that time there were no mesiodistal uprighting springs. They were created by Begg in 1960, to upright teeth in conjunction with ribbon arch type brackets. Without such springs the tip-edge bracket itself would not be practical. Therefore, a simple,

graphic equation can be formulated to relate the main contributions that led to the evolution of the bracket: [44]

DEVELOPMENT OF THE TIP-EDGE BRACKET: [44]

- Personal clinical experience and results of a study done in 1968 led Dr. P.C. Kesling to conclude that differential tooth movement (crown tipping followed by controlled root uprighting) requires that each tooth tip freely either mesially *or* distally— not in both directions.
- The use of round arch wires permits labial or lingual tipping of all teeth.
- During the early stages of treatment, the crowns of all teeth tip distally with the exception of those distal to extraction sites (and mesial to the anchor molars), which tip mesially.
- When teeth are free to move in this manner, it is possible to correct deep anterior overbites and retract dental arches with light (2oz), intraoral elastic and arch wire forces that leave the anchor molars upright and relatively undisturbed.
- By chamfering diagonally opposed corners of the conventional edgewise arch wire slot, it is possible to create an edgewise-type bracket that is programmed to permit either mesial or distal crown tipping and yet still control final crown inclination.
- Because the archwire slot permits initial crown tipping mesially or distally and faces horizontally, the slot and bracket are termed "Tip-Edge" and the technique that takes full advantage of this slot and differential tooth movement with straight archwires, is termed "The Differential Straight-Arch Technique".

FOR AUTHOR USE ONLY

APPLIANCE CONFIGURATION:

TIP-EDGE BRACKETS: [44,36]

- By removing predetermined, diagonally opposed corners from the conventional edgewise archwire slot, the Tip-Edge bracket is created.
- This permits the desired distal crown tipping required for differential tooth movement.
- Pre-adjusted in three dimensions, the Tip-Edge slot permits the use of straight archwires in the majority of cases: both extraction and non-extraction.
- The bracket was further modified by the addition of rotation wings and a vertical slot of 0.020″ x 0.020″ to enhance rotational, tip and torque control.
- Various components of the Tip-Edge bracket are:[35]
    1. Uprighting and torque control surfaces (pre-adjusted).
    2. Central ridges for vertical control.
    3. Wings for rotational control.
    4. Notches or vertical slot to accept Side-Winder springs.

FOR AUTHOR USE ONLY

A- Crown tipping control surfaces

B- Root uprighting control surfaces

C- Vertical and torque control central ridges or pivots

D- Rotational control surfaces or wings

- Tip-Edge brackets are available in single, twin or ceramic versions to meet the preferences of all orthodontists.[44]

- The slots not only permit initial crown tipping but they are also preadjusted to provide the desired final degrees of crown tip and torque.
- The bracket slot is 0.022″ wide between the central ridges which facilitates full yet passive, engagement of the intial 0.018 round arch wire in brackets on teeth that are originally tipped mesio-distally.

II. AUXILIARIES:[44]

- The generous sized vertical slots make possible the use of many auxiliaries throughout the treatment.
    - These may include power pins to accept elastomerics or rotation springs for rapid, physiologic rotation.
    - The most important auxiliaries for use with this system are the mesio-distal uprighting springs or Side-Winders.
    - A unique elastomeric ligature has been developed for the Tip-edge bracket that can provide mesiodistal angular control referred to as a Tip-edge ring. [35]

FOR AUTHOR USE ONLY

CONCEPT AND FUNCTION:[44]

The Tip-Edge concept is to provide an edgewise type bracket that is familiar to all orthodontists and can be used to treat all malocclusions through differential tooth movement. This is accomplished by maintaining everything that is positive associated with an edgewise bracket, especially the labially facing archwire slot and tie wings, while removing that one thing that prevents mesiodistal crown tipping- diagonally opposed corners of the slot itself. This modification of the edgewise slot facilitates the following functions:

1. BITE OPENING:[44]

- Most malocclusions require anterior bite opening, which involves the intrusion of incisor teeth.
- If each tooth is free to intrude along its own path of least resistance, desired bite opening can be accomplished relatively rapidly and with the lightest of forces – approximately 5 gm per tooth.
- Conventional edgewise slots prevent this free root movement and when teeth are tipped mesially or distally, can even cause lateral movements of the roots which further complicates intrusion because of the action of undesired couples and moments created.
- Tip-edge arch wire slots with their one-point contacts with the archwire prevent the creation of such lateral pressures on root surfaces and permit the roots to intrude in an unhindered fashion and it is possible to open the deepest of the anterior bites without the need for extraoral forces.

FOR AUTHOR USE ONLY

2. RETRACTION AND SPACE CLOSURE WITHOUT LOSS OF VERTICAL CONTROL:[44]

- Tip-edge archwire slot permits retraction of anterior teeth without deflection of the arch wire.
- All teeth, even central incisors, tend to tip distally as they are retracted.
- With conventional arch wire slots, this causes binding, first between the slot and the arch wire and secondly, especially in the canine area – it causes the incisal deflection of the wire itself. The central and lateral

incisors are therefore extruded, which may deepen the bite or increase gingival display which is not desirable.

- In the Tip-Edge brackets due to the removal of appropriate corners of the slot, the slot size increases as the tooth tips, with no binding and no deflection.

3. VARIABLE ARCHWIRE SLOT: [44]

- The slot of the Tip-Edge bracket are not only designed to permit crown tipping in one direction but they also become larger as the teeth tip.
- This is due to the inbuilt interior geometry of the slot which is designed such that, relative to the plane of a straight archwire, the vertical dimension within the slot continuously increases with each degree of distal crown tipping.
- The clinical advantages of this feature can be appreciated by comparing what happens to effective slot sizes when Tip-Edge and conventional edgewise brackets are tipped similar amounts.

FOR AUTHOR USE ONLY

The advantages gained are :

a) No binding or arch wire deflection during retraction.
b) Ease of stepping up in archwire size.
c) No inadvertent mesial or distal root movements.
d) Ease of placing rectangular archwires when third order discrepancies exist between the slots and the wires.
e) No need to use nickel titanium or memory wires to avoid discomfort and/or accidental debonding.

4. ANCHORAGE CONSIDERATIONS: [44]

- Extra oral anchorage is absolutely not needed when practicing the differential straight arch technique (DSAT) with Tip-Edge brackets. The forces are so light (2 ounce) that adequate anchorage can be easily found within the mouth.
- Binding, which normally occurs between conventional edgewise slots and archwires during space closure, is eliminated in the Tip-Edge bracket by atleast 90% due to the in-built interior geometry of the bracket itself, wherein the corners of the slots that usually press against the upper and lower surfaces of the archwires as the teeth tip and cause the friction are eliminated.
- In non-extraction cases the design of the Tip-Edge archwire slots automatically sets up anchorage in one arch while permitting free distal tipping in the other arch.

FOR AUTHOR USE ONLY

5. FAIL-SAFE MECHANISM: [44]

- Of great importance and advantage when using Tip-Edge archwire slots is the fact that lack of patient co-operation (not wearing elastics) does not result in negative/undesired tooth movements. The tooth movements merely stop and progress is put on "hold".

6. INTERBRACKET DISTANCE: [44]

- The force delivered to teeth from archwires is inversely proportional to the distance between the brackets- interbracket distance.
- If the teeth are tipped mesially or distally or when the labiolingual inclinations of adjacent teeth vary, relatively short interbracket distances result in the creation and delivery of very high force values during slot engagement with either round or rectangular wires.

- To overcome these problems, orthodontists have elected to use nickel titanium and/or undersized arch wires when second or third order discrepancies exist.
- The tip-edge archwire slot completely eliminates problems caused by interbracket distances. Initially, when using round archwires, the cut-out corners of the slot prevent binding from tipped teeth - torque discrepancies are no concern because of the round wire.
- As treatment progresses and crowns are tipped toward their final positions in the dental arches, slot sizes have increased. This permits passive engagement of full size, rectangular stainless steel wires with zero flexing.
- Each tooth will have either one point or no contact with the archwire. Therefore, "interbracket" distance is, in effect, from molar tube to molar tube.

FOR AUTHOR USE ONLY

AXIAL INCLINATION CONTROL: SELECTIVE, LIMITED AND PHYSIOLOGIC.

One of the most unique and advantageous features of the Tip-Edge archwire slot is its ability to permit controlled root movement that is selective- as to time and location, physiologic and predetermined. [44]

SELECTIVITY: [44]

- Axial tooth control is selective and always under the control of the operator. This refers to both time and location.

- The mere engagement of arch wires, either round or rectangular in cross section, into Tip-Edge archwire slots has no effect on the inclinations of teeth in any directions.
- When axial control, tip, or torque is desired, it is achieved by the addition of Side-Winder springs to those teeth requiring such correction while the other teeth are left undisturbed.
- The application of force is, therefore, selective and adjacent teeth are not "round tripped" by arch wire flexing, promoting both stability and patient comfort.

LIMITATION: [44]

- The design of the Tip-Edge slot automatically limits the degree of mesiodistal uprighting.
- The second order power from the Side-Winder spring causes the tooth to upright mesiodistally.
- As this occurs, the bracket and its slot rotate relative to the stiff, passive archwire. Uprighting continues until the control surfaces within the slot strike the upper and lower surfaces of the archwire. At that point, uprighting ceases.

PHYSIOLOGIC: [44]

- The forces transmitted to the teeth by Side-Winder springs and other auxiliaries are relatively light and continuous.
- They are, therefore, far more physiologic than the heavier, intermittent jolts of force created by second and third order flexing of steel archwires- even though undersized.
- The design of the Tip-Edge archwire slot also makes it impossible to inadvertently deliver high third order torque forces from flexed rectangular archwires.

FOR AUTHOR USE ONLY

- If a torque discrepancy exists between the archwire slot and the arch wire itself, the central ridges will be moved apart vertically causing the bracket to rotate and the tooth to tip mesially or distally within the confines of the periodontal membrane spaces until the force drops to zero. This is referred to as " Bracket escape" and is beneficial, because it allows a zero torqued rectangular archwire to fit into a severely lingually inclined bracket with little binding or discomfort.

REFINED BEGG TECHNIQUE

This technique was introduced by Dr. V. P. Jayade. According to him, no treatment modality is ever perfect. With the passage of time its drawbacks become apparent. Unless the treatment evolves to overcome those drawbacks, it is likely to become stagnant and then die slowly. Refinements become necessary to incorporate new concepts and technological progress. The present day Refined Begg technique evolved from the original teachings of Dr. Begg to overcome the shortcomings of the conventional Begg technique and to assimilate the contemporary thinking and material advances.[32]

FOR AUTHOR USE ONLY

APPLIANCE CONFIGURATION: [32]

A. BRACKETS: [32]

- The brackets used are TP-256-000, or any other having a similar design and dimensions.
- The depth of the slot is 0.020″and its height is 0.045″.
- The dimensions of the bracket base are 3mm x 3mm.

- They must be made of good quality stainless steel sheets of minimum thickness 0.015″ so that the slot does not open during treatment.

BUILT-IN ADJUSTMENTS: [32]

I. INCISOR BRACKETS:

1. Anti-rotational adjustments: [32]

- The rotational control in Begg bracket during the first stage is poor due to the excessive play when an undersize 0.014″ or 0.016″ wire is used in the 0.020″ slot.
- This has been corrected by building an anti-rotational adjustment in the bracket.
- The mesial or distal edge of the bracket is raised away from the tooth surface for the mesio-lingual or disto-lingual correction respectively (i.e for the incisors which are rotated mesio-labially or disto-labially respectively, to start with). Brackets having such adjustments are available ready made.
- They can also be prepared, as suggested by Mollenhauer, by welding a piece of 0.010″ ligature wire on the mesial or distal edge of the bracket base mesh.
- This is an extremely useful modification that greatly increases rotational control of the Begg brackets. It eliminates the need for archwire offsets, which are otherwise required for holding the corrected rotations throughout the treatment.

2. Built-in torque: [32]

- This technique uses Begg brackets with built-in torque adjustment in the brackets, as was recommended by Kameda, which is obtained by raising the incisal or gingival edge of the bracket base away from the tooth surface.

FOR AUTHOR USE ONLY

- The brackets commercially available have a thin metal wedge interposed between the bracket base and the mesh for this purpose.
- When a rectangular ribbon wire is used in conjunction with these brackets, labial or lingual root torque is produced.
- It is not possible to build such an adjustment in a bracket by welding a piece of wire at the incisal or gingival edge because relatively bigger size wires need to be welded since the deflection range required for achieving adequate torque is quite large.
- Such wires lift the bracket base edge too far away from the tooth surface, and therefore reduce the bonding strength.

II. PALATAL BRACKETS: [32]

- These brackets are placed on the palatal surface of upper incisors when palatal elastics from TPA are used for the upper incisor intrusion.

B. MOLAR TUBES: [32]

- Round molar tubes with 0.036″ inner diameter and 6mm in length are routinely used. Oval tubes with 0.072″ x 0.024″ lumen size and 5m length are used on the second molars in the first molar extraction cases.

C. COMBINATION TUBES: [32]

- These consist of a round gingival 0.036″ diameter tube, 6.2 mm in length, and a rectangular (ribbon) occlusal 0.025″ x 0.018″ tube, 5.5 mm in length. These are used when finishing is done with the rectangular wires.

BUILT-IN ADJUSTMENTS IN THE MOLAR TUBES: [32]

FOR AUTHOR USE ONLY

1. UPPER MOLAR TUBES:

- As suggested by Swain, these are fixed perpendicular to the mesial aspect of the upper molar bands, which results in approximately 10° disto-lingual rotational offset.

2. LOWER MOLAR TUBES:

- These are given a lesser offset of approximately 5° disto-lingual rotation.

FOR AUTHOR USE ONLY

EVOLUTION OF COMBINATION BRACKETS

BEGG/CHUN-HOON COMBINATION BRACKET TECHNIQUE

This technique was introduced in the early 1960's. It incorporates all the essential features of both the light wire and edgewise techniques. This versatile combination bracket can be used interchangeably with both techniques. Available in regular and curved bases.[37]

ADVANTAGE: [37]

- In case of transferred patients, the treatment can be continued with either of the technique according to the preference of the orthodontist.
- Ample room provided for edgewise ligature wire.

FOR AUTHOR USE ONLY

MODIFIED FULL-FLANGED COMBINATION BRACKETS

- Modified version offers gingivally extended welding flanges to provide more area for welding.
- It allows the archwire to rest completely within the bracket.

MODULAR SELF LOCKING APPLIANCE SYSTEM

- A VARIATION IN THE COMBINATION TECHNIQUE
-

This technique was introduced by Maxwell S. Fogel and Jack M. Magill in 1976. The key objective was to treat greater numbers, better, faster, and easier, at lower cost; to utilize highly trained paraprofessionals wherever possible; and to use appliances which can

achieve the optimum biologic response. The philosophy of simplicity, economy and flexibility was the motivation behind the introduction of the Modular Self-Locking Appliance System.[38]

The Modular Self-Locking Appliance System is a light wire system using a single pivotal bracket or twin self-locking low frictional attachments. It has clinically demonstrated simplified and securely controlled mechanics for individual and collective tooth movements to attain optimum end results. Development of an adaptable appliance receptacle makes possible the utilization of the best features of the original Combination Technique with the new and improved clinical procedures.

FOR AUTHOR USE ONLY

The components of the system are as follows:

1. INSERT BRACKET: [38]

- The principal module is the Insert Bracket which is made of a special soft stainless steel and appears able to withstand the various demands made upon it.
- The stainless steel insert bracket does not undergo electrolytic changes, although it possesses the desired quality of softness, which brass has. Steel is stronger, generally lasting throughout treatment, and can be opened and closed as many times as necessary.

The elements of the insert bracket are:

- *Archwire chamber (*. 025"):

For maximum performance in light wire therapy, the round archwires float freely in the .025 chamber. The chamber is strategically placed in

relation to bracket wings, permitting adequate tipping of the archwire, setting in motion less restricted
tooth movements.

- *Beaks:*

They are flared, forming a funnel-shaped entrance for the wire. Beaks can be opened and closed for containment and release of the wire.

- *Insert slot* (.020"):

Entrance formed by shape of beaks, facilitates easy access for archwire.

- *Slot apex (*.012")

Constricted portion of funnel, permits snapping in and retention of wire prior to closure of beaks.

- *Seat:*

Base of insert bracket which rests in the grooved wing of the receptacle for stability.

- *Stem:*

Extension of insert bracket fits into the vertical slot and holds insert bracket in position when bent at right angle.

FOR AUTHOR USE ONLY

- *General thickness (.018").*

- *Bracket head (.070"*x .070").

- *Overall length* (.235").

PLACEMENT OF THE INSERT BRACKET: [38]

- The stainless steel insert bracket is easily fitted into the vertical slot of the receptacle. The stem is cinched and bent laterally with a light wire

plier or a dull ligature cutter, pressed snugly under the wing and against the side wall of the receptacle.

- Removal of the insert bracket is also a quick and easy procedure. The stem is staightened and cut; the head is grasped with the flat end of a dull ligature cutting plier; the insert bracket is removed, using the receptacle wing as a fulcrum.

2. RECEPTACLE : [38]

- The receptacle is made in three sizes — Small (.150"), Medium (.180"), Wide (.200")— and is contoured for specific teeth in the anterior and posterior segments.
- The three vertical slots accommodate insert brackets and auxiliaries.
- A single slot is used in the early stages and both mesial and distal slots are used in the finishing stages.
- Because the vertical slots accommodate the insert brackets and auxiliary springs, the receptacles must not be contoured, lest the slots will be narrowed or distorted causing difficulty of component insertion.
- Blockage of vertical slots must be scrupulously avoided during cementation or bonding. This may be avoided by use of wax in slot openings, use of elastic rings around wings of receptacle, and placement of insert bracket prior to cementation.
- The horizontal slot is an elective feature to satisfy those operators who may still be unsure of handling the modular self-locking concept in its totality.

FOR AUTHOR USE ONLY

- It is suggested that the receptacle be placed toward the incisal edge of the band in order to provide sufficient metal backing for the insert bracket.
- The receptacles are routinely spot welded to the bands in two strategic locations, namely the tabs and the body of the attachment.

- Receptacles are also available in either clear or tooth-colored plastic.

3. MOLAR TUBE ATTACHMENT: [38]

- The oval or slightly flat molar tube with mesial hook is an important component of the Modified Combination Technique.
- Molar control and anchorage are definitely more favorable with the oval buccal tube. The oval tube has a vertical slot to assist in molar uprighting or increased molar resistance, when necessary.

FOR AUTHOR USE ONLY

INSERTION OF LIGHT WIRE INTO INSERT BRACKET: [38]

- The .014, .016 or .018 round archwire is snapped into the insert racket with mild finger pressure.
- In special situations involving major malpositions of certain teeth, a wire director may be used to guide the archwire into the insert slot, where it is quickly and easily snap-locked into the circular insert chamber.
- Finally, closure of the insert bracket beaks is accomplished by gently using How pliers. Usually, the cuspid insert brackets are closed first,

followed by the four incisor teeth, a remarkably simple and rapid procedure.

- There is adequate tipping movements and free flowing movement of the attachment along the archwire.

REMOVAL OF ARCHWIRE FROM INSERT BRACKET: [38]

- If the archwire is not to be re-used, it is practical to cut the wire interproximally and slip each segment out of the light wire insert bracket. It is strongly recommended that the used archwire be cut, removed and discarded, because of the simplicity of light wire fabrication and the ease and rapidity of its insertion with the snap-in insert bracket.
- Re-using the old archwire is a waste of time, since most of the vital qualities of the wire have already been dissipated.
- If it is necessary to preserve the existing archwire, removal is accomplished by opening the insert bracket with an insert spreader.
- The insert spreader, an .012 flat-bladed instrument, is carefully fitted into the insert slot and simply pushed forward, opening the slot to its original dimension and preparing the release of the wire.
- The archwire is snapped out of the slot, using a scaler which acts as a miniature crowbar, effectively and gently disengaging the archwire without distorting it.

FOR AUTHOR USE ONLY

MODERN BEGG: A COMBINATION OF BEGG AND STRAIGHT WIRE APPLIANCES AND TECHNIQUES

Begg appliances and appliances of the straight wire type have been known to produce fine orthodontic results. An analysis of these appliances, however, shows that each has unique characteristics which can be advantages or disadvantages in a total treatment program. In order to increase the total effectiveness of a treatment program, it is suggested that the favorable mechanical capabilities of one or more appliance systems be combined into a synergistic type of mechanics. One such treatment approach might involve light, rapid tipping forces to correct gross changes in tooth position at one stage in treatment, while more rigid and precise appliances are used later in treatment to produce maximum tooth detailing and occlusal intercuspation. Such a combination of treatment capabilities enables the practitioner to achieve selectively or collectively, in an optimum way, the various goals for the denture, patient, and doctor.[39]

FOR AUTHOR USE ONLY

The combination of light wire and edgewise techniques has undergone a significant evolution in orthodontics. The *FOUR STAGE LIGHT WIRE APPLIANCE* introduced by Dr. William J. Thompson in 1981 represents the successful collaboration between Begg practitioners and a manufacturer to produce a mechanism with beneficial design features that uses the advantages while avoiding the disadvantages of both the Begg and the Straight wire appliance. The system permits the use of pure Begg mechanics in that part of treatment and in those cases in which it is most effective. It also permits the use of a straight wire appliance in the same cases or in any cases in which a rigid, preangular-

pretorqued finishing procedure is desired. The treatment mechanism is divided into four stages incorporating the usual stages I, II and III of the Begg technique and stage IV includes finishing with the straight wire appliance.[5]

FOUR-STAGE LIGHT WIRE BRACKET CONFIGURATION:[5,39]

- The four-stage light wire bracket fulfills all the requirements of a true combination bracket.
- The bracket incorporates all the advantages of the true Begg light wire technique like the archwire slot permits maximum free tipping movements, little friction, and no binding, with a vertical slot to facilitate uprighting and torquing of the roots.
- The bracket is also designed to translate teeth, has adequate mesial and distal width for control of rotations, provides optimal torquing power, and is preangulated and pretorqued as in a true straight wire system.
- The dual capability of the appliance system is due to a combination bracket design in which the lower third of the bracket is a Type 256 Begg bracket and the upper two-thirds of the bracket is a 0.018 by 0.025 inch straight wire slot with in-and-out positioning, preangulated and pretorqued.
- The gingival or ribbon arch slot is designed to permit maximum crown and root tipping movements and the edge wise slot is designed for precise fine detailing.
- The bracket differs from other combination attachments in that the gingival slot permits unrestricted tipping and the edge wise slot incorporates preangulation, pretorque and in-out correction.

FOR AUTHOR USE ONLY

- Three bracket types provide adequate mesiodistal width for optimal rotations, tipping and torque.

	BODY WIDTH	BEGG SLOT	STRAIGHT WIRE SLOT
Maxillary centrals	3.30	0.020″	0.018″ or 0.022″
Canines,premolars, Maxillary laterals	2.54	0.020″	0.018″ or 0.022″
Mandibular incisors	1.78	0.020″	0.018″ or 0.022″

- The base of the four stage bracket is beveled to reduce the possibility of friction or binding with the arch wire.

FOR AUTHOR USE ONLY

BRACKET PLACEMENT:[5]

- The appliance is set up in the standard manner with the 0.036 inch Begg

tube placed gingivally on the first molars. All Begg slot heights, other than the molars, are dictated by the edgewise slot and, as such, are 1 to 1.5 mm. more gingival than in a routine Begg banding. It is absolutely essential to set up the straight wire slot so that on the straight wire series the wire is level from the molar tube to all other brackets.

- Positioning of the molar tubes is done first. Slight variations in the dimension from molar tube to cusp tip will exist because of anatomic differences, but a cusp-tip-to-tube distance of 3.5 mm. is a desirable starting point.
- If 3.5 mm. is acceptable, then all other edgewise slots must also be at 3.5 mm. except those on the canines and lateral incisors.

- Upper and lower canine brackets are placed gingivally 0.5 to 1 mm. more, depending on tooth size and shape. Such a position promotes canine-protected occlusion.
- The upper lateral incisors are placed 0.5 mm. more incisally to free them from interferences on the working occlusal movements.
- Each tooth must receive the specific brackets designed for it so that angulation, torque, and the in/out compensation are correct.
- The 1 to 1.5 mm. increased gingival positioning of the Begg slot does not seem to affect the bite-opening or tipping characteristics of Begg treatment. Free tipping is made very effective by means of a specially tapered bracket slot.

FOR AUTHOR USE ONLY

BRACKET PRESCRIPTION:[5]

Tooth	Angulation (tip)	Inclination (torque)
Maxillary		
Central incisor	5^0	7^0
Lateral incisor	9^0	3^0
Canine	11^0	-7^0
First premolar	2^0	-7^0
Second premolar	2^0	-7^0
First molar	0^0	-10^0
Second molar	0^0	-10^0
Mandibular		
Central incisor	2^0	0^0

Lateral incisor		2^0	0^0
Canine		5^0	-11^0
First premolar		2^0	-17^0
Second premolar		2^0	-22^0
First molar		0^0	-25^0
Second molar		0^0	-30^0

ADVANTAGE:

- An advantage of the combination system bracket is the potential in transfer of cases under treatment with either of the technique.

COMBINATION ANCHORAGE TECHNIQUE

Experience and advances in design and technique have greatly enhanced combination orthodontic techniques. Improvements have made the delivery of treatment more effective and reduced the problems with appliance adjustment and esthetics. Some of these improvements are in the bracket itself, which has been modified for efficiency and esthetics. A technique of orthodontic mechanics called Combination Anchorage Technique (CAT) introduced by Dr. William J. Thompson in 1988, with his experience with the Four-Stage Light Wire appliance represents an advancement in the combination orthodontic techniques. The technique was designed to broaden the treatment effectiveness of the orthodontist by providing a combination of orthodontic technical capabilities. Use of the two different bracket slots provides a simple and efficient means to vary (1) anchorage (dynamic or static), (2) movement (tipping or bodily), (3) technique (light wire or straight wire), (4) resistance (one tooth or multiple teeth), and (5) treatment compensation (skeletal or dental).[40]

FOR AUTHOR USE ONLY

Clinical experience with combination brackets since 1978 provided with extensive knowledge regarding the expanded capabilities of the technique. What was originally believed to be a modernized Begg system evolved into a true combination anchorage technique.

APPLIANCE PHILOSOPHY: [40]

- With combination treatment it is possible to use light wire mechanics at their optimum for rapid anterior alignment, maximum retraction of incisors, and superb bite opening.
- At the desired point in treatment, the anchorage resistance can be altered by changing slots, wire size, and friction to produce maximum edgewise control and resistance in a specific area of the appliance.
- The variable anchorage capability is extensive. It can be structured to permit tipping of all teeth in one or both arches to correct midline discrepancies.
- It also can be designed to move posterior teeth mesially or distally and to retract or limit retraction of anterior teeth.
- The control of movement is made possible by use of different types of tooth movement and by establishing variable magnitudes of resistance in the different bracket slots at a specific location in the appliance.

FOR AUTHOR USE ONLY

IDEAL REQUIREMENTS OF A COMBINATION BRACKET: [40]

- To optimize the capability of the combination treatment, it is essential that the combination anchorage brackets be designed to produce optimum light wire and/or optimum straight wire movements.

- The gingival slot provides the most efficient light-force tipping movement because it closely resembles a true Begg ribbon arch-type bracket. It produces maximum speed, maximum tipping, minimum pain, the least amount of friction, and maximum effectiveness for auxiliary uprighting and torquing springs.
- The design of the edgewise part of the bracket must facilitate optimum three-dimensional edgewise treatment. It must have three-dimensional movement capabilities built into the slot for torque, tip, and compensation of anatomic width.
- The bracket must be wide enough for adequate rotation and torque control, and the contour must be esthetic and nonirritating to the tissue.

FOR AUTHOR USE ONLY

SHORTCOMINGS OF THE ORIGINAL COMBINATION BRACKET: [40]

- The original combination brackets proved to be bulky, weak, and esthetically unattractive.
- Although capable of Begg and straight wire mechanics, design deficiencies made them less effective than typical Begg or edgewise brackets.
- There were problems with pinning, rotations, slot closure, and occlusal interference.

COMBINATION ANCHORAGE TECHNIQUE (CAT) BRACKET DESIGN: [40]

- The CAT bracket design has proved to be clinically excellent for both light wire and straight wire treatments. It is comfortable and esthetically pleasing to the patient.
- It has a 0.022 x 0.035-inch gingival or ribbon arch slot and either a 0.018 x 0.025-inch or 0.022 x 0.028-inch straight wire edgewise slot.
- An enclosed vertical slot also is incorporated into the bracket for use with uprighting or rotating springs, elastic or surgical fixation hooks, and for attachment of the tandem or double arch wires.
- All brackets are identified by color coding dots at the distogingival aspect. Maxillary brackets are red and mandibular brackets are blue.
- Bracket size and contour have been reduced. Comparison with other brackets indicates that the profile of the new bracket is less bulky occlusally, buccolingually, and on the peripheral edges.
- These changes have reduced lip irritation caused by bracket bulk, reduced irritation caused by sharp corners, and practically eliminated distortion of lower premolar tie wings caused by occlusal interference.
- Gingival extension of all pads and brackets has been reduced to make placement more accurate and occlusal interference less likely.
- A redesigned pin slot and bracket pad have simplified placement and retention of pins. Phase I and II treatments are now completed with the same type of pins.
- Special pins are available to reduce friction during tipping movements of an arch wire in the gingival slot.
- New auxiliary extension pins have been contoured for lip comfort and modified to hold an elastomeric ring or an elastic.

FOR AUTHOR USE ONLY

- Use of these extension pins with elastomeric rings permits fixation of tandem arch wires and are also used as surgical ligation hooks.

BRACKET PLACEMENT: [40]

- The technique for placement of the combination brackets is similar to that used for all straight wire appliances. The edgewise slot should be parallel and at the same level as the interproximal contact points of the teeth in normal occlusion.
- For molars it is normally recommended that the rectangular tube be 3.5 mm from the molar cusp tip.
- All other teeth should be at the same level as the molars except canines and upper lateral incisors. These are altered to provide clearance during mandibular excursions. The edgewise slot should be located 4 mm from the cusp tip on canines and 3 mm on the maxillary lateral incisors.
- When the edgewise slots are leveled with a continuous straight wire, it is important that the canines be slightly extruded and maxillary lateral incisors slightly intruded. These positions will establish optimum canine rise and protect the smaller lateral incisors during lateral and protrusive excursions.

FOR AUTHOR USE ONLY

BRACKET PRESCRIPTION: [40]

- The CAT bracket retains the three-dimensional edgewise capability of the earlier combination brackets.
- However, maxillary incisor brackets now can be obtained with varying degrees of torque.
- Maxillary canine torque has been reduced to 0°. This change produces less prominence of the canine roots on the labial plate and it positions

the lingual surface for a gentle rise in lateral excursions as desired with mutually protective occlusion.

- Torque on the lower premolar has been changed from 17° on the first premolar and 20° on the second premolar to a standard of 19° for both. This change reduces both inventory requirements, identification problems, and does not adversely affect positioning or intercuspation.

Tooth	Angulation (tip)	Inclination (torque)
Maxillary		
Central incisor	5^0	7^0
Lateral incisor	9^0	3^0
Canine	11^0	0^0
First premolar	2^0	-7^0
Second premolar	2^0	-7^0
First molar	0^0	-10^0
Second molar	0^0	-10^0
Mandibular		
Central incisor	2^0	0^0
Lateral incisor	2^0	0^0
Canine	5^0	-11^0
First premolar	2^0	-19^0
Second premolar	2^0	-19^0
First molar	0^0	-25^0
Second molar	0^0	-30^0

LINGUAL ORTHODONTIC APPLIANCES

With the advent of bonding of attachments directly to the teeth, the elimination of the band material kindled a desire for even more cosmetic appliances, which first resulted in clear plastic brackets and tooth-colored ceramic brackets. A current approach has been bonding brackets directly on the lingual surfaces of the teeth.

In 1975, Dr. Craven Kurz of Beverly Hills, California, became convinced that a lingual bonded edgewise appliance was feasible and would make a significant contribution to adult orthodontics. He created his own lingual appliances by modifying labial appliances, and utilized them on a limited basis in his practice. His initial results encouraged him to continue his work in lingual orthodontics. In 1976, research and development on a nonedgewise lingual appliance was initiated by Ormco in close cooperation with Dr. Alexander (Jim) Wildman in Eugene, Oregon. This program pointed out many of the difficulties involved with a totally lingual fixed appliance. Later in 1976, Dr. Kurz submitted specific designs and concepts to the U.S. Patent Office for the patent rights to his unique edgewise lingual appliance. Shortly thereafter, Dr. Kurz and Ormco began an intensive program to develop the appliance and bring it from a dream to reality.[41]

FOR AUTHOR USE ONLY

In 1978 detailed studies were conducted, measuring the morphology of the lingual surfaces of the teeth in order to reduce the size of the bracket bases and facilitate lingual bonding. The lingual arch form was studied topographically, to establish lingual torque and tip angulations in reference to accepted labial measurements. From this accumulated data and using a design concept to assure proper function and patient comfort, the initial lingual edgewise prototype

was manufactured in 1979. [41]

In December 1979, Dr. Kinya Fujita, of Kanagawa Dental University,Japan, published an article describing appliances with a lingual bracket design and mushroom shaped archwires. His work confirmed the experiences of Dr. Kurz and Ormco that, certainly with refinements, lingual appliances were a viable adjunct to the orthodontist's armamentarium. [41]

KURZ LINGUAL APPLIANCE

This was introduced by Dr. Craven Kurz in association with Ormco in 1982. [41]

FOR AUTHOR USE ONLY

BRACKET CONFIGURATION: [41]

- The brackets are composed of a hardened stainless steel with a single design, varying in width with each tooth in the arch.
- The brackets are brazed to a diffusion bonded foil/mesh base. The bonding base is contoured to approximate the lingual morphology of each individual tooth.
- Since there is such a wide variety of lingual anatomy, additional adaptation is achieved in the laboratory on a custom tooth-by-tooth basis at the time of the indirect bonding setup.
- Brackets have an .018" archwire slot which parallels the occlusal plane.
- Elastomeric ligatures are more commonly used due to their ease of application while wire ligatures are indicated in specific instances.
- Brackets are provided with various degrees of torque, angulation, and bracket thickness. These characteristics were determined after

extensive study of lingual morphology, and by comparing this anatomy and tooth position to accepted standards for labial appliances.

- Maxillary anterior brackets incorporate a bite plane designed into the incisal edge of the bracket. The bite plane is parallel to the archwire and the occlusal plane. [41]
- All brackets have a gingival ball hook which greatly facilitates elastic ligature placement, rotation control, and placement of intra- and intermaxillary elastics.
- Patient selection is of the utmost importance, and patients with short clinical crowns on the maxillary anteriors present definite limitations. Maxillary incisor lingual crown heights of less than 6mm will not permit sufficient space for bonding the brackets to avoid gingival impingement and still finish with 1 to 2mm of overbite. [41]
- Mandibular bicuspids also present a limitation to lingual bonding. Frequently, the lingual cusps, even on fully erupted teeth, have less than the 4mm of crown length necessary to place the bracket. Since these lower bicuspids are not visible on most patients, they can usually be banded without losing the "invisible" aspect of the appliance.
- Banding of the Mandibular posterior teeth, with the use of buccal segmental wires and lingual attachments, has become a common and preferred option.
- The preferred mechanotherapy approach has evolved into a combination using both buccal and lingual posterior segments, with the lingual brackets alone being confined to the incisors, canines, and maxillary bicuspids.

FOR AUTHOR USE ONLY

- This arrangement— termed the "crossover technique" or "buccolingual segmental technique"— appears to offer the best features for both esthetics and anchorage control. [41]
- In this technique, first and second molars are banded with a terminal lingual tube welded to the first molar band. Buccal tubes are also placed on the molar bands.
- Bonded or banded buccal brackets are occasionally placed on maxillary second bicuspids, if the patient's smile permits.
- In the mandible, buccal attachments on the bicuspids add considerably to the options of the buccal segmental approach and do not usually compromise esthetics.
- Thus, the mandibular buccal segment consists of bonded buccal brackets on the bicuspids and a banded first molar with both buccal and lingual attachments, thus providing the option of bypassing the bicuspids on the lingual, with the lingual archwire terminating in the first molar lingual tube.

FOR AUTHOR USE ONLY

MODIFICATION OF LINGUAL TECHNIQUE

This technique was introduced by Dr. Stephen F. Paige in 1982.[42]

BRACKET DESIGN CRITERIA: [42]

- The first important factor to be considered in designing lingual attachments is that interbracket distance is reduced on the lingual. Therefore, the bracket must be designed to be as narrow as possible mesiodistally.
- Keeping the buccolingual distance minimal would also have advantages, since a small buccolingual dimension will increase interbracket distance. In crowded situations, more brackets could be placed at the initial appointment if the bracket profile is small.
- Secondly, as a consequence of decreased bracket width, mesiodistal root control becomes more difficult. Cuspid and bicuspid uprighting after closure of extraction spaces requires efficient mechanisms for uprighting. A possible solution to this problem is the use of vertical slots for arch auxiliaries.
- The third factor to consider is the topography of the lingual surfaces of the maxillary and mandibular anterior teeth. The lingual contours of the anterior teeth seem to vary a great deal.
- Because of the concave and convex surfaces, the amount of torque supplied to the tooth by the bracket will be very sensitive to its occlusal-gingival placement. A very small change in the occlusal-gingival placement can produce a large change in root torque.

FOR AUTHOR USE ONLY

Amount of torque will relate to occlusal gingival placement of lingual bracket.

- It has been argued that this problem could be solved by indirect bonding procedures by the bracket manufacturer. If a bracket comes off during treatment, or if the orthodontist is unable to indirect bond all of the teeth at the initial appointment, he is still required to bond the attachment directly.
- Indirect bonding by the bracket manufacturer for an edgewise "straight-wire" technique must take into account many factors normally in the control of the clinician. Many patients need dental compensation and appropriate torque values for skeletal patterns other than Class I. Overcorrection of tooth angulation and inclination also would be difficult for proper finishing, if bracket placement is determined by the manufacturer. Thus, until future advances make precision direct bonded placement of the lingual bracket possible by the orthodontist in clinical situations, a preangulated, pretorqued "straight-wire" edgewise approach to bracket design appears to be impractical at this time.
- A fourth factor for consideration would be ease of insertion, ligation, and removal of the archwires. A very satisfactory solution in the technique is the incisal/occlusal placement of the archwire. The use of vertical slots could permit the use of pins to increase ease of ligation.

FOR AUTHOR USE ONLY

BRACKET CONFIGURATION: [42]

- According to the author, the bracket that satisfies these design criteria nicely is a Begg bracket and is available from many manufacturers.

- It is as narrow as possible and has a vertical slot for use of auxiliaries.
- Lingual tooth contours on the maxillary and mandibular teeth are much less of a factor because torque control can be achieved by properly shaped torquing auxiliaries, much like conventional Begg mechanotherapy.
- Ligation can be achieved with steel ligatures, elastic modules, or pins.
- The slot can be oriented in an occlusal-incisal direction to ease archwire placement and removal.
- Placement of the bracket is sensitive only to the incisal-gingival placement because angulation and inclination can be achieved with the use of auxiliaries.
- The TP 256-500 Begg bracket with the slot oriented in a gingival direction was used initially.
- The bracket currently in use is the Unipoint combination bracket (Unitek), with the slot oriented in the occlusal-incisal direction. The horizontal slot is not routinely used during treatment and is used only to aid in unraveling of crowded anteriors.
- The Unipoint combination bracket was used because of the need to have a gingival "wing" to place elastic modules on continuous elastic chains.

FOR AUTHOR USE ONLY

CREEKMORE LINGUAL APPLIANCE

This technique was introduced by Dr. Thomas Creekmore in 1989. According to the Dr. Creekmore, an acceptable lingual orthodontic appliance system must include the following key elements:[43]

(1) A mechanical appliance that aligns teeth from the lingual aspect as efficiently as a labial appliance.

(2) A means of positioning brackets precisely to create a "near" straight-wire appliance on the lingual aspect.

(3) A consistent and accurate indirect bonding technique.

(4) A selection of preformed arch wires complete with canine-premolar offsets.

(5) Specially designed pliers with longer handles and offset beaks.

(6) Lingual bracket-removing pliers.

(7) Offset torquing keys.

(8) Training for the orthodontist and staff to develop their lingual treatment technique so that it becomes as routine as their labial treatment.

To satisfy these requisites, a lingual mechanical appliance (Conceal) was developed by Dr. Creekmore. [43]

FOR AUTHOR USE ONLY

APPLIANCE CONFIGURATION: [43]

- The foundation of the design is the opening of the arch wire slots to the occlusal aspect rather than to the lingual aspect.The occlusal approach makes arch wire insertion, seating, and removal easier than arch wire insertion with lingually opening slots.

- An additional benefit of an occlusal slot is that the arch wire will not pull out of the slot with space-closing mechanics. This eliminates the special time-consuming ligation techniques (double-over ties) necessary for lingually opening slots.
- A critical breakthrough for this technique was the design of premolar and molar brackets, with occlusal tie wings projecting mesially and distally instead of labiolingually. These tie wings change the direction

of the ligature pull 90°, effectively seating the arch wire in the bottom of the slot.

- Anterior brackets use this same design feature to enhance the quality of their ligation. The occlusal tie wings have mesial and distal undercuts that parallel the bottom of the slot They also change the direction of the pull of the ligature to seat the arch wire into the bottom of the slot.
- Conceal brackets are designed around the Unitwin bracket "centered slot" concept. The Unitwin bracket is, in effect, a single bracket without tie wings in the center of a 0.045 inch twin bracket.
- It uses the advantages of both single and twin brackets by allowing maximum interbracket distance for optimal tip and torque functions, while providing twin tie wings for rotation control. The mesiodistal bracket side does not necessarily dictate the arch wire slot dimensions.

Each Conceal bracket has three different slot widths for the three different functions of tip, torque and rotation.

FOR AUTHOR USE ONLY

- Tip control in an occlusally inserting system is analogous to rotation control in a labial system. Both depend on the length of the lever arm and the quality of the ligature tie to seat the arch wire in the bottom of the slot. For twin brackets, the length of the lever arm is the width of the bracket. For brackets with rotation wings, the lever arm is the width of the bracket plus the length of one rotation wing.
- From labial experience, it is known that adequate rotation control requires a minimum lever arm of about 0.100 inch in length. Therefore, adequate tip control in an occlusally inserting system requires a slot width of 0.100 inch. The floor of the slot for all of the

Conceal brackets is about 0.100 inch, which provides excellent control in the tipping plane.

- The width of the slot for rotation is about 0.070 inch. Rotation control in an occlusal-slot system results from the engagement of the arch wire in the slot and does not depend on the ligature tie. It is analogous to tip control in a labial system.
- Torque control is the same for both systems. The width of the slot for torque is about 0.035 inch. The arch wire can twist as it exits the slot E-F. Torquing play is a function of the size of the rectangular or square arch wire relative to the size of the rectangular arch wire slot. Width of the slot is not a factor in torquing play. The ligature tie does not influence torquing play.
- For anterior teeth at the level of the arch wire slot, space available for brackets on the lingual surfaces is about two thirds of that available on the labial surfaces. The resulting decrease in interbracket distance means that smaller arch wires must be used to develop proper forces.
- The Conceal system slot is therefore 0.016 inch horizontally and 0.022 inch vertically, a size determined by computer models to produce forces comparable to those of traditional labial designs. Reduction of the slot size to more closely match the desired smaller arch wire size provides more precise rotation and torque control.
- In addition to the occlusal opening and optimum slot design, Conceal meets the difficult challenge of small working space. Since the lingual anterior tooth surfaces are inclined about 45° to the occlusal plane, the space available for brackets is smaller gingivally than occlusally.
- Anterior brackets have a Y configuration, with a single tie wing projecting gingivally and twin tie wings projecting occlusally. This

FOR AUTHOR USE ONLY

design provides the same selectivity of ligation as a regular twin bracket, but it is easier to ligate. Canine and lateral incisor brackets have built-in T hooks for intramaxillary and intermaxillary elastics.

ADVANTAGES OF LINGUAL BRACKETS OVER LABIAL BRACKETS[43]

- Facial surfaces of the teeth are not damaged from bonding, debonding, adhesive removal, or decalcification from plaque retained around labial appliances.
- Facial gingival tissues are not adversely affected.
- The position of the teeth can be more precisely seen when their surfaces are not obstructed by brackets and arch wires.
- Facial contours are truly visualized since the contour and drape of the lips are not distorted by protruding labial appliances.
- Most adult and many young patients would prefer "invisible" lingual appliances if costs, treatment times, and results were comparable to those of labial appliance treatment.

FOR AUTHOR USE ONLY

EVOLUTION OF SELF-LIGATING BRACKETS

A *self-ligating bracket* is defined as "A bracket, which utilizes a permanently installed, moveable component to entrap the arch wire." Self-ligating brackets may be classified onto two categories: passive and active.[45]

1. PASSIVE BRACKETS:[45]

- They use a rigid, moveable component to entrap the arch wire.
- Tooth control with passive brackets is determined solely by the fit between bracket slot and arch wire.
- As a result, tooth control frequently is compromised with undersized arch wires housed in what is essentially an arch wire tube.

FOR AUTHOR USE ONLY

2. ACTIVE BRACKETS:[45]

- They use a flexible component to entrap the arch wire.
- This flexible component constrains the arch wire in the arch wire slot and has the ability to store and subsequently release energy through elastic deflection.
- This gentle action imparts a light but continuous level of force on the tooth and its supporting structures, resulting in precise and controlled movement.
- The homing action of the flexible component may be described as the ability of the bracket to reorient itself and its accompanying tooth in three dimensions until the arch wire is seated fully in the arch wire slot: the "home" position.

- Any subsequent rotation, tipping, or torquing during tooth movement of any kind results in the labial deflection of the flexible component and reactivates this homing behavior.

HISTORICAL PERSPECTIVE OF SELF-LIGATING BRACKETS: [45]

The concept of a self-ligating orthodontic attachment is not new.The first patent for a self-ligating attachment, the Boyd band bracket, was filed by Charles. E. Boyd in 1933. Shortly thereafter James W. Ford filed a patent for the Ford Lock design, which was manufactured briefly by the Dee Gold Company of Chicago, Illinois. Production was abandoned because the design was too bulky and expensive to be commercially viable. The bracket was reintroduced in 1951 by his son William F. Ford, but it was marketed primarily for the Johnson twin wire technique. An overview of the evolution of Self-ligating brackets is given in the following table:

FOR AUTHOR USE ONLY

Patent File Date	Bracket	Mode Of Action	Moving Component
1933	Boyd band bracket	Passive	Rigid sliding bar
1933	Ford Lock	Passive	Rigid rotational lock
1935	Russell appliance	Passive	Rigid sliding lock
1953	Schurter device	Passive	Rigid locking pin
1957	Rubin device	Passive	Rigid hinged plate
1966	Branson	Passive	Rigid rotational screw
1972	SPEED system	Active	Highly flexible spring clip

1972	Edgelok bracket	Passive	Rigid sliding cap
1979	Mobil-Lock bracket	Passive	Rigid rotational disk
1986	Activa bracket	Passive	Rigid rotational arm
1995	Time bracket	Passive	Rigid rotational arm
1996	Damon bracket	Passive	Solid indented slide
1998	TwinLock bracket	Passive	Solid labial slider
2000	In-Ovation	Active	Flexible spring clip
2004	Damon 3	Passive	Rigid solid slide

I. RUSSELL LOCK EDGEWISE BRACKET: [45]

- The first self-ligating bracket, the Russell lock edgewise attachment, was developed by New York Orthodontic pioneer, Dr Jacob Stolzenberg, in 1935.
- This bracket had a flat head screw seated snugly in a circular, threaded opening in the face of the bracket.
- For the orthodontist arch wire changes were quick and simple. The horizontal screw could be loosened or tightened with a small watch repair screw driver to obtain the desired tooth movement.
- Loosening allowed bodily translation on round wire, while tightening facilitated root torquing with a rectangular or square wire.
- The mechanism of this revolutionary bracket was in stark contrast to the traditional approach of tying steel ligatures tightly around each bracket.

II. EDGELOK BRACKET :[45,46]

- In 1972, Dr. Alexander J. Wildman of Eugene, Oregon, developed the Edgelok Bracket.

FOR AUTHOR USE ONLY

- The bracket had a round body with a rigid labial sliding cap. A special opening tool was used to move the slide occlusally for arch wire insertion.
- When the cap was closed over the arch wire with finger pressure, the arch wire slot was converted to arch wire tube by closing off the labial portion of the slot, thereby entrapping the arch wire.
- The rigidty of this outer fourth wall rendered the bracket passive in its interplay with the arch wire.

ADVANTAGES OF THE EDGELOK BRACKET: [46]

1. *Strength.* The basic shape of Edgelok is a slot surrounded on four sides by contoured metal surfaces. The material is cast chrome alloy, a much harder material than machinable 300-series stainless steel. Because of this hardness and the large welding flange, it is all but impossible to shear Edgelok from a band .

FOR AUTHOR USE ONLY

2. *Smooth to tissue.* One of the benefits of the button shape is that it is a smooth, round surface which is exposed to the tissue. The absence of ties is an obvious additional benefit.

3. *Low profile.* Edgelok's button shape allows it to be large where needed for strength, but small in the critical areas. The occlusal boss can be reduced as much as necessary to accommodate the occlusion. It is even possible to use Edgelok as a bite block.

4. *Automatic locking and unlocking*. Elimination of the tedium of tying was one of the basic advantage of Edgelok.

5. *Reliable action*. Because of Edgelok's strength and design characteristics, the locking action is extremely reliable. It clicks open and it clicks shut. There is no intermediary position.

6. *Complete control in all planes of space* . Practicing orthodontics with Edgelok was like practicing with an eighth-inch buccal tube on each tooth. One is forced into complete bracket engagement at all times. The bearing or rotating surface was similar to the bearing surface of the traditional siamese bracket.

LIMITATIONS OF EDGELOK BRACKET: [46]

- Passive brackets like the Edgelok bracket have limitations in their ability to control tooth movements because of their total reliance on the fit between the arch wire and the bracket slot.
- This means that tooth control is compromised when undersize wires are used.

The Edge-lock was the first passive self-ligating bracket design to enjoy any sort of commercial success.

FOR AUTHOR USE ONLY

III. THE MOBILE-LOCK BRACKET :[45]

- About 2 years later, Dr. Franz Sander introduced the Mobil-Lock bracket.
- The bracket had a semi-circular locking mechanism .
- The Mobil-Lock bracket required a special tool to rotate the semi-circular labial disk into the slot open or closed position.
- As with the Edgelok, the passive outer wall transformed the arch wire slot into a tube that loosely contains the arch wire.

IV. SPEED BRACKET SYSTEM:[47]

The SPEED appliance system was developed by Dr. Herbert .G. Hanson in 1975 and introduced in 1980. Hanson in 1975 ,

combined Angle's edgewise appliance with his own concept of developing both a dynamic and self-ligating appliance. This resulted in a spring-loaded, self-adjusting ligatureless design that possessed the unique quality of retaining and actively influencing control of the arch wire within the arch wire slot. The acronym SPEED has been chosen to identify the appliance and the system of treatment which is continuing to evolve with its use. The name is derived from the descriptive terms *SPRING-LOADED, PRECISION, EDGEWISE, ENERGY, AND DELIVERY,* all of which describe features of the design. In the ongoing quest for perfection, the SPEED appliance has undergone numerous refinements since its introduction in 1980.

FOR AUTHOR USE ONLY

DESCRIPTION OF THE SPEED APPLIANCE: [47]

The main components of the appliance are a multislotted bracket body, a spring clip, and specially shaped foil-mesh bonding bases.

THE BRACKET BODY: [47]

- The bracket body has:
  1. Four slots
  2. A shallow triangular groove
  3. Short welding flanges
  4. No gingival tie wing.
- The four slots are:
  1. An 0.018 by 0.025 inch horizontal arch wire slot opens to the labial and has an 0.75 inch lingually centered radius to its lingual wall.

2. An 0.017 by 0.017 inch horizontal slot opens to the lingual, with its gingival wall continuous with the occlusal surface of the welding flanges.
3. A vertical spring slot of uniform and appropriate depth for each of five different base curvatures opens to the lingual.
4. A shorter and narrower angled instrument-access slot communicates with the spring slot from the labiogingival aspect.

- The bracket body has a shallow transverse groove on its labial surface a short distance occlusal to the arch wire slot.

THE SPRING CLIP: [47]

- The highly resilient spring clips are formed from a high tensile 17-7 precipitation-hardening 0.005 by 0.060 or 0.005 by 0.072 inch stainless steel strip.
- Each has a short labial arm joined to a somewhat longer lingual arm by an 0.025 inch (radius) curved occlusal portion which has an angle of wrap of 217 degrees 30 minutes when free from external stresses.
- In this "resting" condition prior to assembly, the spring arms converge at an angle of 37 degrees 30 minutes.
- The lingual arm of the spring has an 0.030 inch wide indent centered near its gingival edge which projects labially approximately 0.005 inch.
- After forming and prior to assembly, the springs are precipitation hardened for 1 hour at 900° F. (480° C.).

THE BONDING BASES: [47]

- The bonding pads are just wide enough for a secure laser seam weld to

FOR AUTHOR USE ONLY

each bracket flange.

- As viewed from the labial, the mesial and distal edges of each pad are parallel to one another and angulated relative to the occlusal edge in accordance with the amount of crown tip usually required by the type of tooth to which it has been assigned.
- While these three edges are straight, the gingival edge is curved gingivally in the form of a semi-ellipse.
- The occlusal edge of each bonding pad is cut "level" so that it will be parallel to the long axis of the arch wire slot after pre-angulated welding.
- All pads requiring mesiodistal curvature are bent about a central axis parallel to their mesial and distal edges. Typical bend radii are 0.10, 0.15, and 0.20 inch.
- Premolar pads are given an additional occlusogingival curvature appropriately asymmetrical for conformity to the usual anatomic contours of these teeth.

FOR AUTHOR USE ONLY

BRACKET-SPRING ASSEMBLY: [47]

- After stress relieving and heat hardening, the spring clip is mounted on the bracket body by a special procedure designed to prevent any plastic deformation.
- When the spring is in the slot-closed position, its arms are held apart so as to reduce their angle of convergence by at least 2 degrees. This is, of course, elastic deformation, which means that the mounted spring embraces the bracket body and creates a gingival component of force where its inclined inner surface bears against the occlusolabial corner of the arch wire slot.

- The spring may thus be regarded as attempting to propel itself even beyond the fully closed position which, in fact, it would do if the bracket body surfaces preventing such movement were reduced.
- Mounting the spring on the bracket body in the slot-closed position converts the arch wire slot into a trapezoidal tube having three rigid walls and an elastic inclined labial wall.
- The 0.017 inch lingual horizontal slot also becomes a tube, but the area of the spring forming its fourth wall is next to the restrained lingual arm and is therefore much more rigid. This makes it well suited for receiving square-wire hooks for elastics, ligatures, or even auxiliaries for various types of tooth movement.
- Welding the bracket-spring assembly to its bonding base transforms the vertical lingual slot into a conduit housing the lingual arm of the clip in a close-tolerance (but not frictional) fit.

FOR AUTHOR USE ONLY

THE SPEED APPLIANCE FUNCTION: [47]

The wingless SPEED appliance is unique in its manner of operation due to the presence of the flexible spring clip. This highly resilient spring clip is primarily responsible for controlling tooth movement in all three planes of space through rotation, tip, and torque. Its unique method of delivery ensures a more continuous delivery of force, as well as a reduced level of frictional drag. The SPEED appliance has been designed for precise rotational control about three axes:

1. The occlusogingival axis (rotations)
2. The labiolingual axis (tipping)
3. The mesiodistal axis (torque)

These mutually perpendicular axes intersect at the arch-wire-slot centroid, so that any change in a bracket's attitude (and consequently that

of the tooth to which it is attached) can be described in terms of rotation about one or more of these axes.

V. ACTIVA BRACKET :[48]

- The Activa bracket was introduced by Dr. Erwin Pletcher in 1986.
- The Activa brackets are fully programmed preadjusted brackets with a horizontal slot of .022″ x .022″ and a vertical slot of .020″ x .020″.
- The bracket has an inflexible, curved arm that rotates occluso-gingivally around the cylindrical bracket body.
- The arch wire is retained by a resilient clip that rotates into a retaining groove gingival to the arch wire, positioning two straps labial to the wire and creating a bracket that is very similar mechanically to a molar tube with twin channel caps.
- The clips can be opened and shut with a wide range of commonly used hand instruments including ligature tuckers, flat plastics, and Mitchell's trimmers.
- All brackets have permanent, as well as painted, identification marks.
- Brackets for the anterior teeth have gingival and occlusal tabs to assist orientation relative to the facial axis of the clinical crown.

ADVANTAGES OF ACTIVA BRACKET: [48]

- Low friction between bracket and arch wire.
- More certain full arch wire engagement.
- A vertical slot for hooks, rotational and uprighting springs.
- The brackets are smaller than the twin or mini twin brackets and inturn more esthetic.
- Being true straight wire, can integrate with any of the straight wire bracket within same arch.

FOR AUTHOR USE ONLY

- Arch wire changes are faster and easier because of simple opening and closing of the caps and requires less chair-side assistance.
- Reduced friction causes teeth to move dramatically faster with less force.
- Will accept elastic chains.
- Sliding mechanics work well with this appliance.
- Excellent patient comfort and acceptance.
- It is possible to immobilize a tooth or a group of teeth so that they will not move, by placing an elastic over the arch wire in the slot of any bracket and then closing the cap over the elastic, this makes anchorage control easy.
- Easier oral hygiene and less cross-infection risk because of no ligatures.

FOR AUTHOR USE ONLY

DISADVANTAGES OF ACTIVA BRACKET: [48]

- Higher bond failure rate
- Less convenient with elastomeric chain
- Unfamiliarity
- Harder to hold and seat when bonding
- Partial slot engagement not possible
- Breakage of arch wire retaining clips
- Low friction increases wire displacement

VI. TIME BRACKET :[45,49]

- The Time bracket was introduced by Dr. Wolfgang Heiser, Austria in 1995

- About the size of the conventional bracket, the Time bracket features a curved, rigid arm that wraps occlusogingivally around the labial of the bracket body.
- A sharp instrument is used to pivot the arm gingivally into a slot-open position and occlusally into the slot-closed position.
- The stiffness of this bracket arm prevents any substantial interaction with the arch wire, thereby rendering the Time bracket a passive bracket.

VII. TWINLOCK BRACKET :[45]

- The TwinLock bracket was Dr. A .J. Wildman's second endeavor, after the Edgelok bracket and was introduced in 1998.
- The bracket featured a flat rectangular slide housed between the tie wings of an edgewise twin bracket.
- It is moved occlusally into the slot-open position with a universal scaler. It then slides gingivally with finger pressure to entrap the archwire in a passive configuration.

FOR AUTHOR USE ONLY

VIII. DAMON SL BRACKET : [50,51]

- The Damon SL bracket was introduced by Dr. Dwight H. Damon in 1996.
- Design Criteria for the Damon SL Bracket[50]

The Damon SL bracket was designed to satisfy the following major criteria:

_ Andrews Straight-Wire Appliance concept

_ Twin configuration

_ Slide forming a complete tube

_ Passive slide on outside face of bracket

_ Brackets opening inferiorly in both arches

- They had a slide, which moved vertically on the labial surface of an otherwise fairly conventional twin tie-wing bracket. [51]
- The slide clicked into a positive open or shut position and opened in a downwards direction in both jaws to give a full view of the slot. [51]
- A tiny U-shaped wire spring lay under the slide and clicked into the two labial 'bulges' on the slide to provide positive open and shut positions. [51]
- These brackets were a major step forward, but suffered two irritating problems—the slides sometimes opened inadvertently and they were prone to breakage. [51]

FOR AUTHOR USE ONLY

IX. DAMON 2 BRACKET:[51]

- The imperfections in the Damon SL bracket led to the development of Damon 2 brackets, which retain the same vertical slide action and U-shaped spring to control opening and closing, but place the slide within the shelter of the tiewings.
- Combined with the metal injection moulding manufacture, which permits closer tolerances, these developments have almost completely eliminated inadvertent slide opening or slide breakage.
- A side effect of this design change has been to reduce the overall size of the bracket to very compact dimensions. This reduced size is an advantage. The larger inter-bracket span produces lower forces, but the secure full engagement retains much better control than for a conventional bracket of the same width.

- There remains scope for further improvement. Also, whilst the slide closure is very secure, the close fit causes the force required for closure to vary.
- One unique and useful feature of the slides on Damon brackets is that they open inferiorly in both arches in order to give an unobstructed view of the slot.

X. GAC In-Ovation bracket:[51]

- These are very similar to the SPEED bracket in conception and design, but are of a twin configuration .
- They are a good, robust design, and no breakage of the clips has been personally experienced or reported. Some relatively minor disadvantages in bracket handling are apparent.
- First, some brackets are hard to open. This is unpredictable, but more common in the lower arch where the gingival end of the spring clip is difficult to visualize. Excess composite to the gingival of lower brackets can be hard to see and may hinder opening.
- Secondly, these brackets are extremely easy to close inadvertently before the archwire is in position and the downwards direction of closure makes this more likely in the lower arch.
- Thirdly, the security of closure of the flexible clip can be overcome by some rectangular nickel-titanium wires, which can cause spontaneous opening of the clip.
- Lastly, it is possible—as with the Damon2 bracket slides—to incompletely open the clip and discover the need for the final fraction of opening through difficulty with removing a thicker archwire.

EVOLUTION OF BRACKETS BASED ON MATERIALS

Brackets can be classified depending on materials used for manufacturing them as:

1. Metallic
    a. Gold alloys
    b. Stainless steel
    c. Cobalt Chromium
    d. Titanium
    e. Magnetic
2. Plastic
    a. Fibre Glass reinforced
    b. With metal slot
3. Ceramic
    a. Monocrystalline alumina
    b. Polycrystalline alumina
    c. Zirconium

FOR AUTHOR USE ONLY

METALLIC BRACKETS:[44]

Before Angle began his search for new materials, orthodontists made attachments from noble metals and their alloys. The metals used were:

- Gold (atleast 75%, to avoid discoloration)
- Platinum
- Iridium
- Silver alloys

ADVANTAGES:

- Esthetically pleasing
- Corrosion resistant
-

DISADVANTAGES:

- Lack flexibility and tensile strength.
- Inappropriate for complex machining and joining when used in the traction bars.

In 1887 Angle tried replacing noble metals with German silver, a brass. An accomplished metallurgist, Angle knew that he had to prepare the German silver "according to the use for which it was intended." To obtain the desired properties he varied the proportions of Cu, Ni, Zn around the average composition of the Neusilber brass as well as by applying cold working operations at various degrees of plastic deformation. As a result, Angle made it rigid enough for jack and traction screws, elastic enough for expansion arches, or malleable enough for bands.

FOR AUTHOR USE ONLY

DISADVANTAGES OF GERMAN SILVER:

- Unsightliness
- Lack of reproducibility
- Mechanical and chemical properties of German silver were below modern demands.

The material that was to truly displace noble metals was stainless steel.

I. STAINLESS STEEL: [44]

The family of steels that contain more than 12% chromium owes its success in the manufacture of instruments and attachments to combined high mechanical strength, acceptable appearance, and chemical resistance. Stainless steel entered dentistry in 1919, being introduced at Krupp's Dental Polyclinic in Germany by the company's dentist, F. Hauptmeyer. Angle used it in his last year (1930) as ligature wire. By 1937 the value of stainless steel as an orthodontic material had been confirmed.

STRUCTURE AND COMPOSITION: [44]

There are several classes of stainless steels, each characterized by a specific crystal structure determined by composition. The composition of stainless steel used for orthodontic attachments is as follows:

FOR AUTHOR USE ONLY

METAL	PERCENTAGE	FUNCTION
Chromium	16-26%	Protects the steel from corrosion with an impermeable, corrosion-resistant layer of chromium oxide.
Nickel	3-14%	Stabilizes at lower temperatures into a homogenous and corrosion-resistant austenitic phase.
Manganese	2-18%	Replacement for nickel to stabilize austenite phase in nickel free alloys.
Molybdenum	0.6-4%	Substitutional metal.
Carbon	0.02-0.15%	Added for strength in powder metallurgy.

Phosphorus	0.03-0.2%	Allows the use of a lower temperature for sintering.
Sulphur	0.01-0.15%	Allows easy machining of wrought parts.
Silicon	0.35-1%	Improves resistance to oxidation and carburization at higher temperatures and to corrosion in some media.

CLASSIFICATION:

Steels are classified according to the American Iron And Steel Institute (AISI) system. The steels, which have AISI numbers beginning with the numeral 3, are all austenitic; the higher the number, the less nonferrous the alloy. The letter L signifies a lower carbon content.

FOR AUTHOR USE ONLY

1. AUSTENITIC STEELS (300 series): [44]

- It is called austenitic because the metal has an austenite structure at room temperature.
- Structurally these steels are solid solutions, which offer better corrosion resistance of all the stainless steel alloys.
- It has a face-centered cubic structure that renders these steels nonferromagnetic.
- Most of the stainless steel metal brackets are made form the austenitic steel. AISI series 303, 304, 316 and 317 are the major classes of Stainless steel being used by manufacturers.

- The emerging trends in Stainless steel usage, is the increasing use of 304L and 316L (Low Carbon content) steel in bracket manufacturing.

2. MARTENSITIC STEELS (400 series): [44]

- In addition to carbon, other elements were added to stainless steels to stress their microstructure and thereby increase tensile strength.
- Stronger but less corrosion-resistant alloys were the result and thus should be used only for short contacts with the oral environment.
- These steels are used primarily for instruments that require sharp or wear-resistant edges.

FOR AUTHOR USE ONLY

3. FERRITIC STEELS: [44]

- The name *ferritic steel* derives from the fact that the microstructure of these steels is the same as that of iron at room temperature (BCC).
- The difference is that in ferritic steel, chromium is substituted for some of the iron atoms in the unit cells.
- The modern "super ferritics" which belong to this category, contain 19-30% chromium and are used in several nickel-free brackets.

4. DUPLEX STEELS: [44]

- Duplex steels consist of an assembly of both austenite and ferrite grains.
- Besides iron these steels contain molybdenum and chromium, and they have a lower nickel content.

- Their duplex structure results in improved toughness and ductility as compared to ferritic steels, while their yield strength is more than twice that of austenitic stainless steel and are highly stress-corrosion resistant.
- Duplex steels have been used for the manufacture of one-piece brackets e.g Bioline "low nickel" by CEOSA, Madrid.

5. PRECIPITATION-HARDENABLE(PH) STEELS: [44]

- The PH steels can be hardened by heat treatment, unlike most stainless steels.
- The process actually is an aging treatment, which promotes the precipitation of some elements purposely added.
- Because of its high tensile strength, 17-4 PH stainless steel is widely used for "mini" brackets.
- The manufacturer Ormco has used the 17-7 PH stainless steel for the Edgelok brackets.

FOR AUTHOR USE ONLY

6. COBALT-CONTAINING ALLOYS: [44]

- Several cobalt-containing alloys are commonly used in orthodontics, both for wire and brackets.
- Alloys such as Elgiloy and Flexiloy contain a large proportion of nickel while, others are almost nickel free, having been developed to replace their allergenic counterparts.
- These nickel-free steels are used primarily to manufacture attachments, such as Prestige (Pyramid Orthodontics), Nu-Edge LN (TP Orthodontics), and Elite- Opti-MIM (Ortho- Organizers).
- These alloys generally are corrosion resistant.

II. TITANIUM:[52]

The problems of nickel sensitivity, corrosion, and inadequate retention were solved with the introduction of a new, pure titanium bracket (Rematitan) that was competitive in cost to stainless steel brackets.

PROPERTIES:

- Its one-piece construction requires no brazing layer, and thus it is solder and nickel-free.
- A computer-aided laser (CAL) cutting process generates a myriad of micro- and macro-undercuts, making it possible to design an "ideal" adhesive pattern for each tooth.
- Such patterns can allow for the differing occlusal and torsional forces that occur on specific teeth (e.g., anterior teeth vs. second bicuspids).
- The laser undercuts eliminate the need for additional chemical treatment of the base, such as silanization, which can increase bond strength to an undesirable level.
- Titanium and titanium-based alloys have the greatest corrosion resistance of any known metals (except pure gold and platinum, which are too soft and expensive for orthodontic use).
- Rematitan brackets are made from a pure, medical-grade titanium that has advantages in miniaturization over stainless steel because of its greater strength (made possible by special cold-working processes) and its lower elastic modulus.
- In addition, lower anterior brackets can be chamfered to avoid occlusal interference in deep-bite cases.

FOR AUTHOR USE ONLY

- Single-piece construction allows the lowest possible bracket height, since clinical in-and-out depths remain the same. This makes the miniaturized appliance even less conspicuous.
- A low bracket profile can be helpful in assessing lip balance during treatment, especially in cases of lip insufficiency and protrusion. Bulkier labial appliances, including ceramic brackets, can produce a false assessment of lip posture.
- Many patients prefer the appearance of the silver-gray titanium brackets over shiny, reflective stainless steel. The matte finish on the Rematitan bracket, when wet, absorbs light and takes on a subtle luster that blends better with the shade of the tooth.
- Titanium also has low thermal conductivity, and thus alleviates the sensitivity to extreme temperature changes often experienced by patients wearing metal appliances.
- It imparts none of the metallic taste of stainless steel brackets.
- Some clinicians have found titanium brackets to be superior even to stainless steel brackets in sliding mechanics.
- An oxidation treatment of the titanium bracket, in addition to creating chemical and mechanical passivity, hardens the bracket slot. Surface hardness of the slot is one of several factors that can reduce the coefficient of friction.
- The smooth, Teflon-like surface of titanium is due to a thin layer of titanium oxide, which prevents direct contact between the metallic atoms on the surfaces of the wire and the bracket, thus reducing interatomic adhesion and friction.

FOR AUTHOR USE ONLY

III. MAGNETIC BRACKETS:[53]

These were introduced by Terushige Kawata in 1987.

PROPERTIES: [53]

- The magnetic material that was first employed clinically was a cast alloy consisting of 25% to 30% chromium, 15% to 25% cobalt, and 45% to 60% iron. The size of the magnet originally used was 6 x8 x 2 mm.
- Although the CoCr alloy was easy to process and had sufficient magnetic force to facilitate tooth movement, it was believed that its size was too great to be used intraorally.
- Recently, a new material has been developed that contains a rare earth metal (samarium) and cobalt. By using this new material, the appliance can be made smaller in size while enhancing the force level.
- This new magnet is a powdered metallurgically processed intermetallic compound of cobalt and rare earth metals.
- The magnet has at the present time the highest available coercivity and maximum energy product. It is further suited to flat circuits and resistant to outer demagnetizing fields.
- The new material has recently been further improved so that a magnetic force of 50 g has been increased to 250 g while at the same time the volume of the material has decreased.
- This force magnitude is sufficient to move canines and other teeth.
- The samarium-cobalt magnets were prepared by attaching an edgewise bracket with an 0.018″ slot to the surface of the magnet and plating it with chromium to prevent corrosion of the magnet and with nickel to solder the bracket to the surface.

FOR AUTHOR USE ONLY

- The layer of nickel allowed the edgewise bracket to be soldered to the surface below 500° C.
- Finally, a mesh base was soldered onto the rear of the magnetic bracket, allowing the bracket and magnet combination to be bonded to the surface of the teeth by means of a direct bonding system.
- The magnetic brackets were designed to form an ideal arch in both the maxilla and mandible on the completion of treatment.
- The size of the magnetic bracket varies as follows:

(1) The mesial distal length of the mandibular incisor bracket is 4 mm, the vertical width is 3.5 mm, and the labiolingual thickness is 3 mm

(2) The mesial distal length of the maxillary incisor bracket is 7 mm, the vertical width is 3.5 mm, and the labiolingual thickness is 3 mm.

- Because of the tooth size, the mesial-distal length is the variable.
- With this arrangement, each bonded bracket can be used for mesiodistal magnetic force.
- However, if the distance between the malpositioned teeth is over 3 mm and the magnetic force is thus not sufficient to retract these teeth, a power chain can be added to assist the magnetic force in the initial stage.
- When these teeth come closer together, that is, within 3 mm, the power chain is removed and the additional retraction can be done through the available magnetic force. This procedure has reduced treatment time as compared with traditional methods.

FOR AUTHOR USE ONLY

PLASTIC BRACKETS:[44,54]

Plastic brackets were first marketed in the early 1970's. Initially constructed from acrylic and later polycarbonate, their

acceptance by orthodontists as an aesthetic alternative to metal brackets was short lived because of the inherent
problems.

DRAWBACKS OF PLASTIC BRACKETS:[54]

- Staining and odours.
- Lack of strength and stiffness resulting in bonding problems.
- Tie wing fractures.
- Permanent deformation or creep. This occurs when a material is subjected to a constant load over an extended period of time and is particularly important for thermoplastic materials such as polycarbonate resins.
- Polycarbonate bracket slots distorted with time under a constant physiologic stress (2000gm.-mm) rendering them insufficiently strong to withstand longer treatment times or transmit torque.
- In a simulated intra-oral situation Harzer et al. reported significantly higher torque losses and lower torquing moments with polycarbonate brackets compared to metal brackets. They recommended that manufacturers should provide data on the distortion to be expected in polycarbonate brackets, which must be offset by additional torque, or that the bracket torque should be omitted from the technical specification.

MODIFICATIONS OF PLASTIC BRACKETS: [54]

- To compensate for the lack of strength and rigidity of the original polycarbonate brackets, high-grade medical polyurethane brackets and polycarbonate brackets reinforced with ceramic or fibreglass fillers

FOR AUTHOR USE ONLY

and/or metal slots have been recently introduced and are becoming increasingly popular.

- Polycarbonate brackets with metal reinforced slots demonstrate significantly less creep than conventional polycarbonate brackets although torque problems still exist.
- Approximately 15% loss in torque over 24 hours has been observed with both ceramic reinforced and metal lined polycarbonate brackets. However, the performance of these brackets is significantly better than polycarbonate brackets and they probably have the potential to challenge ceramic brackets with future development.
- When comparing torque deformation characteristics of seven commercially available plastic brackets against stainless steel brackets, Sadat-Khonsari et al. showed that metal slot reinforced brackets were subjected to the lowest degree of deformation, followed by pure polyurethane, pure polycarbonate and fibreglass reinforced polycarbonate brackets.
- Ceramic reinforced polycarbonate brackets showed the highest deformation under torque stresses. The addition of ceramic and fibreglass in the plastic brackets also failed to improve the torque stability of the polycarbonate brackets and pure polyurethane brackets showed no significant difference from pure polycarbonate at optimal torque.
- A comparison with stainless steel brackets illustrated that plastic brackets are only suited for clinical application if they have a metal slot.
- Self-ligating aesthetic brackets are a further recent development. Polycarbonate self-ligating brackets have been shown in vitro to

FOR AUTHOR USE ONLY

generate significantly greater static and kinetic frictional forces than stainless steel self-ligating brackets but are comparable to conventional stainless steel brackets.

CERAMIC BRACKETS:[54,55,56]

Ceramic brackets were introduced in the 1986, offering many advantages over the traditional aesthetic appliances. Ceramic brackets provide higher strength, more resistance to wear and deformation, better colour stability and, most important to the patient superior aesthetics. Ceramic brackets are available in a
variety of morphologies including true Siamese, semi-Siamese, solid and Lewis/Lang designs and also various appliance systems including Begg and variable force
ligation brackets.

FOR AUTHOR USE ONLY

PROPERTIES OF CERAMIC BRACKETS:[55]

- Ceramics are renowned for their hardness and for their resistance to high temperatures and to chemical degradation. The atomic structure that imparts these advantages also accounts for the most glaring fault of ceramics— their brittleness.
- Metals can be deformed considerably without fracturing, even in the presence of significant impurities and at sharp intersections. This ductility is a function of their non-oxidized atomic structure. When metals are stressed, a shifting at grain boundaries causes a redistribution and relief of the stress.

- In contrast, ceramics used in orthodontic brackets have highly localized, directional atomic bonds. This oxidized atomic lattice does not permit shifting of bonds and redistribution of stress. When stresses reach critical levels, the interatomic bonds break and material failure occurs. This is called "brittle failure".
- Ceramic compounds, unlike metals, are also susceptible to crack propagation caused by minute imperfections or material impurities. High-strength ceramics can fail relatively easily when cracks or imperfections allow for local concentrations of stresses.
- Although sharp intersections can be tolerated by stainless steel alloys, the geometry of ceramic brackets is critical in preventing stress build-up and brittle failure. Rounded intersections minimize the likelihood of brittle failure occurring at force levels substantially below the material's maximum strength.

FOR AUTHOR USE ONLY

COMPOSITION OF CERAMIC BRACKETS:

All the currently available ceramic brackets are composed of aluminum oxide. One type is polycrystalline, made of sintered or fused aluminum oxide particles, and the other contains a single crystal of aluminum oxide.

Polycrystalline ceramic brackets:[55]

- Polycrystalline brackets are manufactured by blending aluminum oxide particles with a binder so that the mixture can be molded into a shape from which a bracket can be cut.
- The molded mixture is heated to temperatures in excess of 1800°C to burn out the binder and fuse the particles together. This fused part is

then machined with diamond cutting tools to provide the slot dimensions and other critical tolerances.

- The machined bracket must be heat-treated to remove surface imperfections and relieve stresses created by the cutting operations.
- Optical properties and strength are incompatible for polycrystalline ceramics. The larger the ceramic grains, the greater the clarity or translucency. However, the material tends to become weaker when the grains reach a size of about 30 microns.
- Polycrystalline brackets begin as aluminum oxide particles of about .3 microns, which are fused to produce ceramic grains of 20-30 microns. Heat treatments after machining must be carefully controlled to prevent further grain fusion, which could detract from physical properties.
- The main advantage of the polycrystalline manufacturing process is its ability to mold brackets— a relatively inexpensive operation that yields large quantities.
- The disadvantages of this molding process are the presence of structural imperfections at grain boundaries or of trace amounts of impurities. Impurities in quantities as minute as .001 percent or slight imperfections can serve as foci for crack propagation under stress.
- The molding process and heat treatment produce fused aluminum oxide with grain boundaries that refract light, resulting in a degree of opacity.
- Production of polycrystalline brackets is less difficult, and hence these brackets are more readily available at present.
- The most apparent difference between polycrystalline and single-crystal brackets is in their optical clarity.

FOR AUTHOR USE ONLY

Single crystal ceramic brackets:[55]

- Single-crystal ceramic brackets are manufactured by an entirely different process. Single crystals of man-made sapphire are produced by making a molten mass of aluminum oxide at temperatures in excess of 2100°C.
- This mass is slowly cooled to allow a carefully controlled crystallization. The resultant crystal is purer than its natural counterpart.
- Orthodontic manufacturers purchase these large single crystals and mill them into the shapes and dimensions of various brackets, using ultrasonic cutting techniques, diamond cutting, or a combination of the two.
- After milling, the sapphire crystals are heat-treated to remove surface imperfections and to relieve stresses induced by the milling operations.
- The primary advantage of single-crystal manufacturing is the elimination of possible stress-inducing impurities or imperfections.
- The disadvantage is the difficulty and added expense of milling the third-hardest known material. This involves the development of new technology— with its inherent new problems.
- Single-crystal brackets have noticeably more optical clarity than polycrystalline brackets.

FOR AUTHOR USE ONLY

Polycrystalline zirconia brackets:[54]

- Polycrystalline zirconia brackets (ZrO2), which have the greatest toughness amongst all ceramics, have been offered as an alternative to alumina ceramic brackets.

- They are cheaper than the monocrystalline ceramic brackets but they are very opaque and can exhibit intrinsic colours making them less aesthetic.
- Good sliding properties have been reported with both stainless steel and nickel-titanium archwires along with reduced plaque adhesion, clinically acceptable bond strengths and bond failure loci at the bracket/adhesive interface.
- However, Keith et al. found no significant advantage of zirconia brackets over polycrystalline alumina brackets with regard to their frictional characteristics.

DISADVANTAGES OF CERAMIC BRACKETS:[54]

- Difficulty in bonding and bond strength
- Increased frictional resistance
- Bracket breakage and fracture resistance
- Iatrogenic enamel damage
- Debonding

FOR AUTHOR USE ONLY

EVOLUTION OF BRACKETS BASED ON BIOMECHANICAL CONSIDERATIONS

1. EFFECT OF BRACKET SLOT SIZE IN THE EDGE WISE SYSTEM: [57]

- The use of rectangular arch wires in rectangular bracket slots was introduced by Edward Angle in the late 1920's with his edgewise arch mechanism.
- The original appliance was designed for use with gold arch wires, and the 22 x 28mil bracket slot size was designed to accommodate rectangular arch wires of approximately the same dimension.
- In Angle's concept of treatment, sliding teeth along archwires to close extraction sites was unnecessary, because extractions for orthodontic purposes were not done.
- Torquing movements were important and a major goal of appliance design was efficient torque.
- The appliance was engineered to produce appropriate force and a reasonable range of action in torsion when gold archwires of 22 x 28 dimension were used with narrow brackets
- When gold arch wires were replaced by stainless steel arch wires, Angle's original engineering calculations were no longer valid because steel wires of the same dimension were more stiffer.
- An alternative was to redesign the edgewise appliance, optimizing the bracket slot size for steel.
- A reduction in slot size from 22 to 18 mil was advocated for this purpose.

FOR AUTHOR USE ONLY

- Even with this smaller slot size, full dimension steel wires still produced slightly greater forces than the original edge wise system, but the properties of this appliance system were close to the original.
- Good torque is possible with steel wires and 18mil edgewise brackets.
- The next important consideration with the introduction of steel wires was the use of undersized arch wires in edgewise brackets to reduce friction if teeth are suppose to slide along the arch wire.
- As a practical matter, sliding teeth along an arch wire requires at least 2 mil of clearance, and even more clearance may be desirable.
- The 18 mil wire offers excellent clearance in a 22-slot bracket, but fits tightly in a 18-slot bracket.
- The original 22-slot bracket therefore would have some advantage during space closure but would be a definite disadvantage when torque is needed later.
- Hence, slot size plays an important role in determining arch wire changes and sequence at each stage of treatment.

FOR AUTHOR USE ONLY

I. EFFECT OF BRACKET WIDTH: [57]

- Control of root position with an orthodontic appliance is needed in two circumstances: when the root of a tooth needs to be torqued faciolingually, and when mesiodistal root movement is needed for proper paralleling of teeth when spaces are closed, as at extraction sites.
- In the former instance, the necessary moment is generated within the bracket, and the key dimension are those of the arch wire; in

the latter circumstance, the moment is generated across the bracket, and bracket width determines the length of the moment arm.

- The wider the bracket, all other things being equal, the easier it will be to generate the moments needed to bring roots together at extraction sites or to control mesiodistal position of the roots in general.
- The bracket width assumes even greater practical significance when the extraction site is to be closed by sliding teeth along an arch wire, and friction between the wire and bracket is encountered. Frictional resistance to sliding is affected by the force with which the bracket contacts the arch wire and the contact angle between the wire and the bracket.
- The wider bracket reduces both the force needed to generate the moment and the contact angle and is thus advantageous for space closure by sliding.
- Wider brackets have a partially offsetting disadvantage in that the wider the bracket on a tooth, the smaller the interbracket span between adjacent teeth, and therefore the shorter the effective length of the arch wire segments between supports.
- Reducing the span of the wire segments in this way greatly decreases both the springiness of the arch wire and its range of action.
- For this reason, the use of extremely wide brackets is contraindicated. The maximum practical width of a wide bracket is about half the width of a tooth, and even narrower brackets have an advantage when teeth are malaligned, because the greater interbracket span gives more springiness.

FOR AUTHOR USE ONLY

II. SURFACE QUALITIES OF BRACKETS: [57]

- Bracket surfaces are important in friction.
- Most modern orthodontic brackets are either cast or milled from stainless steel, and if properly polished have relatively smooth surfaces comparable with steel wires and sliding with these brackets is reasonably good.
- Titanium brackets were introduced primarily because they eliminate the chance of an allergenic response to the nickel in stainless steel brackets. They have surface properties like those of titanium wires and sliding with titanium brackets is problematic due to the increased surface reactivity, particularly if titanium arch wires are also used.
- Ceramic brackets also show frictional resistance to sliding. The polycrystalline ceramics have considerably rougher surfaces than steel brackets. This rough but hard ceramic material is likely to penetrate the surface of even a steel wire during sliding, creating considerable frictional resistance. Even the single crystal brackets have increased frictional resistance to sliding. To solve this problem of friction, ceramic brackets with metal slots have been introduced

FOR AUTHOR USE ONLY

CONCLUSION

As we know that treatment principles are mainly based on science but art is also a part of it. Through the years, the advent of new system of brackets have been pounded into the field of orthodontics, which has guided and at the same time misguided the clinician in his planned mechanotherapy. This can't be attributed only to the in built properties of the material but also to the extent of basic knowledge a clinician owes regarding that particular system.

As such there is no known universal bracket system to treat all types of malalgined teeth, yet there are varieties of system available in which the clinician should judge and make judicious use of it. Providing a "*Right Treatment for a Right Patient using a Right Appliance at a Right Time"*.

INTRODUCTION

"**Speech is the use of systematized vocalization to express verbal symbols or words**." (Sheridan)

Speech is a very sophisticated autonomous and unconscious activity. Speech in matured man is a learned habitual neuromuscular pattern, which makes use of anatomical structures, designed primarily for respiration and deglutition. Because oro-dental morphological features also may influence an individual speech, the dentist should therefore recognize the possible role of prosthetic treatment on speech activity.

The loss of teeth and supporting structures alters the main articulatory cavity and produces a marked effect on the speech pattern proportionate to the location and magnitude of alterations. An empiric approach to the phonetic factor in denture construction frequently places the burden for compensating for speech changes for the adaptability of the tongue. Additionally significant is the fact that the speech mechanism is highly susceptible to degenerative diseases. If dentures are to contribute effectively to the functions of speech, dentists should utilize studies in the speech science field to augment their clinical knowledge of the phonetic factor in denture construction.

FOR AUTHOR USE ONLY

Corrections of faulty speech is the primary task of the speech specialist, but the complexity of the voice producing mechanism implores the services of the allied health sciences successful treatment of defective speech usually requires close co-operation between the speech therapist and the practitioner in some branch of the medical or dental professions.

A missing bicuspid will permit a lateral emission, which is intolerable to the precise speaker or singer. A missing anterior tooth will permit an anterior emission, which impairs speaking until an accommodating articulations pattern in learned. Gross removal of gingival tissues denies the tongue its usual soft tissue contact and because a potential escape of the air stream between the interspaces of the exposed root portions of the teeth. Mechanical movement of the tooth or teeth in the maxillary arch, will increase or decrease the area for speech articulations. Speech rehabilitations following dental treatment is an obligations of the profession, and failure to include phonetics in the dental curriculum is not coincident with the high standards established by dental educators to provide maximum health service.

The poorly contoured replacement for a single tooth can cause speech impediment, and larger prosthetic restorations fabricated without regard for speech articulations will impair speech articulations will impair speech until an accommodating articulations pattern is learned. A very high percentage of the English speaking sounds are produced by contact of the tongue with some portions of the palate and teeth. Since these contact areas are either replaced or covered by the complete denture, speech rehabilitation for the edentulous patient becomes the serious task of the prosthodontic. Failure to contour the palate to accommodate normal tongue contact usually results in poor speech for a period of several days or several weeks, depending upon the amplitude of the patient and the discrepancy in the palatal contour. This inarticulate period, generally accepted as "getting used to denture", could be markedly reduced or completely eliminated if proper attention were given to palatal contour at the time of the waxed trial denture try in. Faculty speech is never desirable, even for a short period of time. It is unpleasant for the listener, embarrassing to the patient, and adds to the burden of adaptation is dentures. Contour of the palate for proper tongue. Contact is not difficult, time consuming, or expensive, however it does require some knowledge of the fundamentals of phonetics and a precise knowledge of the normal tongue contact areas for speech articulation.

FOR AUTHOR USE ONLY

NEUROPHYSIOLOGICAL BACKGROUND

A very complex neuro-physiological mechanism governs the production of speech. A large number of oral mechanosensitive receptors (tactile and kinesthetic) are involved in its motor control. Therefore, all prosthodontic treatment will, more or less, have an influence on speech performance because a great number of these structures will be involved.

Speech production includes large number and sequences of innate and learned motor acts produced in sequences of 12-16 sounds/sec in a rhythmic behavior. It has been hypothesized that less cortex area is required for processing of skills as they become automatic. Once automatized, speech control becomes localized in certain areas such as the pre-motor and motor cortex. For the precise movements executed in speech production the pyramidal motor system has the primary role.

Feed back plays a dynamic and flexible role in the control of most motor events, including sequencing and timing of speech movements, there seems to be a subconscious but learned type of pattern recognitions, or feedback, of afferent information is used is guide central pattern generator (CPG's) and a central program. Other neural networks are also very active in the rapid transformations of the shape of the oral cavity from one fixed configurations to another. Proprioceptive mechano-sensitive afferents will establish the timing of certain aspects of the very fast motor pattern and will, in synergy with cortical information, generate the final motor output and rhythm. A precise co-ordination between different articulators is essential for the final sound production.

FOR AUTHOR USE ONLY

A prerequisite for the satisfactory speech sounds and adaptation in an intact general feed back system, with auditory feedback is regarded as a very important mechanism. When impaired hearing is present, speech production will deteriorate. Adaptation after an oral rehabilitation also may create problems in the formation of new neuromuscular pathways.

It appears that adaptation to complete dentures may be explained by feedback mechanism related to speech motor programming. Initially, a complete denture wearer attempts to over come problems related to the new prosthesis by the help of auditory and oro-sensory feed back during function. After a while only, the patient will be aware of remaining articulating difficulties, which often are related to certain

specific sounds. The listener (dentist) is, however, not able to detect any speech production disturbances. At this stage, there are still sensory stimulations from orofacial afferents to central areas. Finally, if the process of adaptation proceeds, the patient will not be aware of any articulatory difficulties or distortional sounds due to the prosthesis. New speech production central engrams have been established, and adaptation and / or habituation to the complete dentures occur.

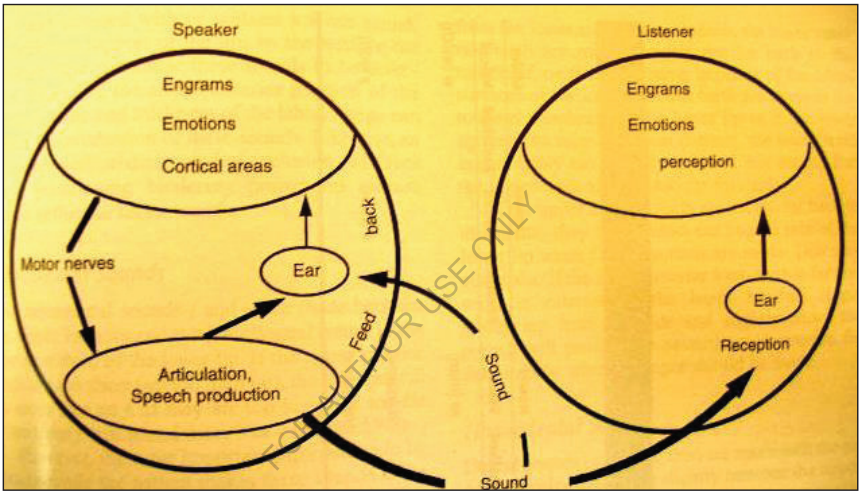

Fig 1: Speech production and communication

INNERVATION OF SPEECH

The principal motor nerves for the muscles of speech are the trigeminal (V^{th} cranial), facial (VII^{th} cranial), glossopharygeal (IX^{th} cranial), Vagus (X^{th} cranial), and hypoglossal (XII^{th} cranial). These innervate the laryngeal muscles (vagus), muscles of the soft palate (mandibular division of the trigeminal and vagus), pharyngeal muscles (Glossopharyngeal and Vagus), muscles of the tongue (hypoglossal), and muscles of the periphery of the mouth (facial) in order to obtain motility, to control tonus, and, in turn, to generate and withstand pressure.

The speech mechanism is characterized by motility, by the capacity to exert pressure, by the capacity to resist pressure, and by the ability of the talker to identify through habitual pressures against familiar structures the conditions for a particular sound. The motor innervations involved derives from three pathways; the cortico-bulbar pathway, extra pyramidal paths, and cerebellar paths. The first of these, the corticobulbar-corticospinal, or pyramidal tract permits the conscious control of precise movements required, e.g., in the articulation of speech sounds. This tract becomes important in the relearning of speech habits to accommodate new intra oral structures. The extra pyramidal tract also conveys some voluntary impulses as well as the control of muscle tonus, the regulation and inhibition of opposing sets of muscles, and the coordination of depth of breathing, tension of vocal folds, the lips, the cheeks, the tongue, and the pharyngeal walls. The third pathway, from the cortex to the speech muscles, is the cerebellar one, the route of the automatic coordination. This one takes over much of speech after childhood until violent changes in the speech mechanism or the functioning of the mechanism are introduced.

FOR AUTHOR USE ONLY

COMPONENTS OF SPEECH

Kantner and West divided speech into 5 components:-

Respiration, phonation, resonations, articulations and neurologic integrations, Chierici and Lawson added audition, or the ability to hear sounds, to this list. The successful performance of these functions is necessary for the production of acceptable speech.

1. RESPIRATION:-

During respiration, inhalations and expirations are approx. equal in duration and the airflow is regular and repetitive. During speech, however, the inhalation phase is shortened and the exhalation phase in prolonged and not repetitive. In normal discourse, the volume and pressure of the expelled air is comparable to the vegetative breathing. Upward movement of the diaphragm with contraction of the costal cartilage and contiguous musculature creates an intrapulmonary pressure which is greater than atmospheric pressure, thus permitting air to be expelled from the lungs. Prolongation of exhalation is achieved by the valve mechanism along the laryngeal, pharyngeal, oral and nasal components of the respiratory tract these valves impede the expired air and help to create speech signals. Subglottic pressure is maintained by the balanced elasticity between the inspiratory intercostals musculature and the expiratory abdominal musculature. If the vital capacity of lungs is compromised, as in emphysema, speech will be perceived as "breathy". The poor projections of the voice, in such cases are due to the reduced volume and pressure of the expired air.

FOR AUTHOR USE ONLY

2. PHONATION:-

The larynx provided the first level of constrictions for controlling the respiration air stream. The primary function of vocal cords is to protect the lungs and the lower respiratory tract from inhalation of particulate matter. This mechanism requires a simple, forceful approximation of the vocal folds. Speech, conversely, requires a multitude of positions, varying tensions and vibratory cycles, and an intricate co-ordination of the vocal folds with other structures. If the vocal folds are partially or completely adducted or closed, they impede the expired air. With the proper degree of tension and sufficient sub-glottal pressure, the vocal cords may set in vibration and thus impart phonation to air stream. Where as phonation is essential

for certain speech sounds, other speech signals do not require phonation, hence, the vocal folds are abducted or open. The tension and position of vocal folds will, in part, determine the pitch of the phonated sound. In the production of low pitched sounds, the vocal folds are relatively thick and flaccid. In high-pitched sounds, the margins of the approximated folds are thin and tense.

3. RESONATION:-

The sounds produced at the level of vocal folds, is not the final acoustic signal which is perceived as speech. This sound is augmented and modified by the chambers and structures above the level of glottis. The pharynx, the oral cavity and the nasal cavity act as resonating chambers above the level of glottis. The pharynx, the oral cavity and the nasal cavity act as the resonating chambers by amplifying some frequencies and muting others, thus refining tonal quality. The pharynx being a muscular tube, services as a excellent resonating chamber. This tube is formed by 3 closely associated muscles namely: - inferior, middle and superior constrictor. These muscles are unique in that they share common insertions, the medial pharyngeal raphe, but have a different anterior origin. Also, it appears that each muscle constrictor, as well as portions of each muscle can contact selectively. The dimensional changes imparted by this muscular action influence the resonant characteristics of the pulsating air stream as it emerges from the larynx. The velopharngeal mechanism proportions the sound and / or air stream between the oral and nasal cavities and influences voice quality (or the basic sound) that is perceived by the listener. If velopharangeal closure is compromised, or if the structural integrity or relative size of the oral, pharyngeal or nasal cavities has been altered, voice quality can be compromised.

FOR AUTHOR USE ONLY

4. ARTICULATION:-

Amplified, resonated sound is formulated into meaningful speech by the articulators, namely, the lips, tongue, cheek, teeth and palate, by changing the relative spatial relationship of these structures. The tongue is considered to be the single most important articulator of speech because of its ability to affect rapid changes in movement and shape. The tongue may impede, selectively restrict, and channel the air stream with precise contact against the teeth and palatal areas, thus articulating the basic laryngeal sound, or the non-phonated air stream, into recognizable speech. If oral structures such as the tongue, adjacent soft tissues, jaws or lips, are altered surgically and / or neurologically, articulation may be compromised.

5. NEURAL INTEGRATION:-

Speech is integrated by the central nervous system both at the peripheral and central level. The sequential and simultaneous movements required throughout the speech complex demand precise co-ordination.

Neurologic impairments may compromise, a specific component of the speech such as the vocal folds, soft palate or tongue, or it may indirectly effect the entire speech system. A cerebro-vascular accident may compromise the ability of the patient to comprehend and or formulate meaningful speech, even though all structures used to produce speech are anatomically with in normal limits**.** In addition, a neurologic impairment may produce a specific type of speech deformity. Example: The loss of motor innervations to the soft palate may compromise elevation and velopharangeal closure.

6. AUDITION:-

Audition, or the ability to receive acoustic signals, is vital for normal speech. Hearing permits receptions and interpretation of acoustic signals and allows the speaker to monitor and control speech output. Compromised hearing can preclude accurate feedback and hence, affect speech. Speech development and subsequent speech therapy is hampered in-patient with hearing impairments.

FOR AUTHOR USE ONLY

PHYSIOLOGIC VALVES IN SPEECH PRODUCTION

The primary functions of the respiratory and digestive tract in relation to their secondary function of producing and modifying sounds may be understood by recognizing that the speech mechanism that includes three principal physiologic valves.

1. Valve I , the glottis
2. Valve II, the palatopharangeal region
3. Valve III, the orifice of the mouth.

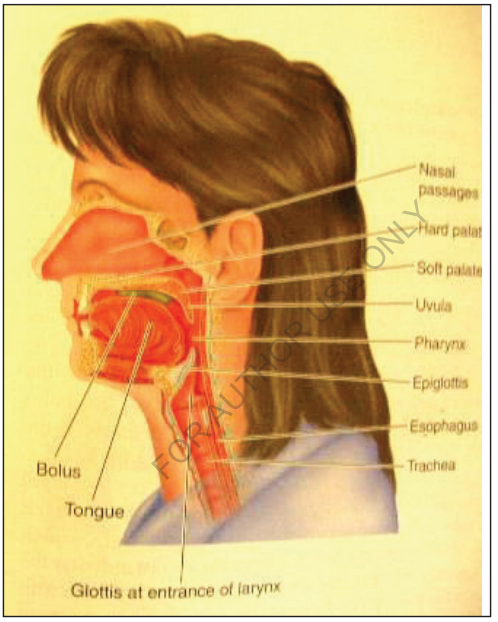

Fig. 2

1. PHYSIOLOGIC VALVE I:-

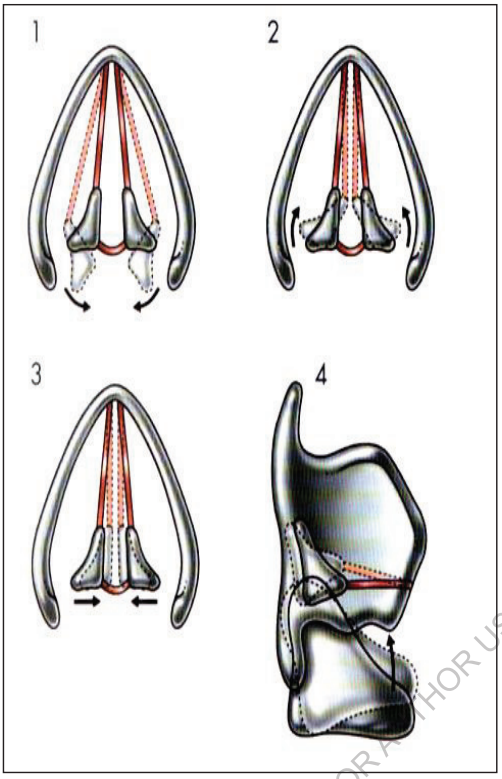
True vocal folds of larynx :- The vibrating mechanism produces vocal tones, and the true vocal folds serve as a valve only in connection with speech sounds that have tone i.e., the voiced sounds other wise, the outgoing stream of air passes through the region of the vocal folds without interference as in normal breathing. The valve mechanically serves to modulate the outgoing breath stream in instance of voiced

sounds only. It is a generator of sound waves which enables man to communicate at a distance as contrasted to the short distance through which one might communicate by whispering.

The larynx, containing the vocal folds that serve intermittently as value I during speech, is composed of three single cartilages and three pairs of cartilages. They are connected by ligaments and moved by muscles, the larynx has a mucous membrane lining that is continued superiorly with the pharynx and inferiorly with the trachea. The cartilages and muscles offer the means for adducting (approximating) and abducting (separating) the true vocal folds and for tensing them (shortening antero-posteriorly) and relaxing them (elongating antero-posteriorly) as shown in figure 3.

The true vocal folds are casually related to voice as apposed to whisper. The folds are attached anteriorly to the thyroid cartilage and posteriorly to the arytenoid muscles. When in a position of rest, as in quiet breathing, the free edges of the folds form an angular opening which has its apex located anteriorly and its base posteriorly the opening or aperture between them when they are not approximated is called rima glottidic. When voice is desired, the folds are approximated, and air is pushed against them from below with sufficient force to blow the edges of these elastic folds apart. The overload of air pressure is momentarily spent. Tension restores the folds to a closed position. This cycle is repeated and becomes quesivibratory. The acoustic output is called voice.

FOR AUTHOR USE ONLY



1 Opening of the rima glottidis by rotation of the arytenoids
2 Closure of the rima glottidis by rotation of the arytenoids
3 Closure of the rima glottidis by approximation of the arytenoids without rotation
4 Tensing of the vocal folds by tilting of the anterior part of the cricoid cartilage

FOR AUTHOR USE ONLY

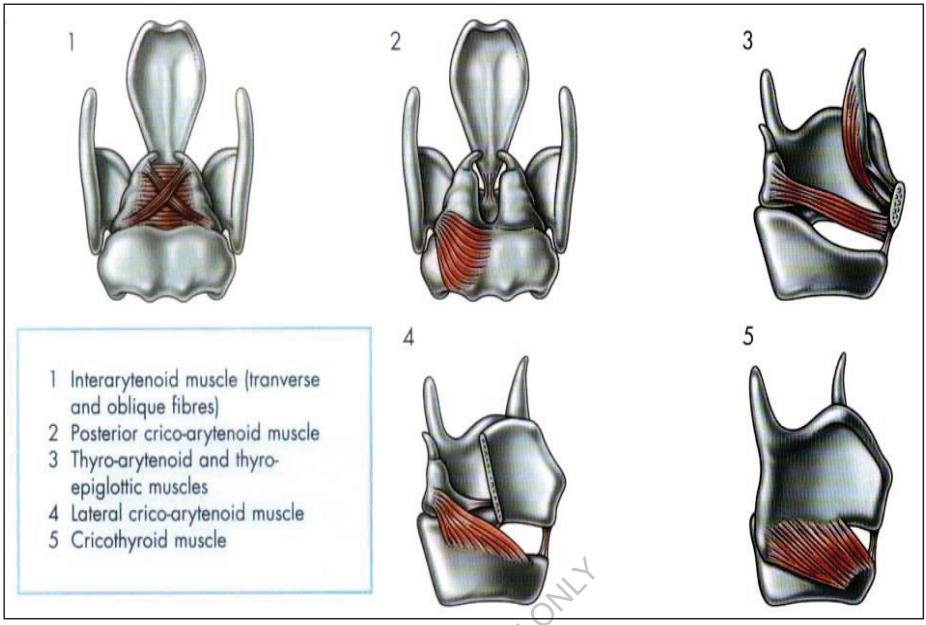
Fig . 3: Moments of vocal cords. The broken outline shows the new position of the vocal folds following muscle contraction.

The muscles that control the vocal folds are divided into two classes:-

a. Those with in the organ itself (intrinsic) and
b. Those that act upon it from out (extrinsic).

The intrinsic muscles have two main functions:-

1. To adduct and abduct the folds
2. To regulate the degree of their tension and length.



FOR AUTHOR USE ONLY

Fig 4: Intrinsic muscles of larynx

The muscle that open the rima glottidis are posterior Crico-arytenoids. They are attached to the posterior surfaces of the arytenoid and cricoid cartilages. Thus, they may rotate the arytenoid cartilages laterally and separate the true vocal cords.

Closure of rima glottides is affected by the arytenoid and lateral crico-arytenoid muscle. They rotate the arytenoid muscle is medially and causes the true vocal folds to be approximated. The arytenoids muscle extends from the posterior and lateral surfaces of one arytenoid cartilage to the corresponding surface of the other. These bring the arytenoids cartilage together, consequently narrowing the rima glottidis. The most important muscle used in lengthening and tensing the true vocal folds is the cricothyroid.

The vocal folds are relaned and shortened by the thyroaryteniod muscle.

The **extrinsic (accessory) muscles** act upon the larynx as a whole, connecting the larynx with the hyoid bone, the sternum, the tongue and the pharynx. By means of these muscles, the larynx may be elevated, depressed and tilted.

2. PHYSIOLOGIC VALVE II:-

Palatopharangeal region:-The pharynx is made up primarily of a constrictor band of broad, flat muscles inserting into a median raphe along its posterior wall. The pharynx may be divided arbitrarily into three parts (as shown in Fig. 5):-

1. **The nasal pharynx** is a continuation of nasal cavity posteriorly; it is bounded inferiorly by the soft palate and terminates along the posterior pharyngeal wall near the atlas (1st cervical vertebra). It's only function is respiratory.
2. **The oral pharynx** is a continuation, inferiorly, of the nasal pharynx to the laryngeal pharynx, i.e. about the level of hyoid bone. It's function are respiratory and digestive.
3. **The laryngeal pharynx** is the inferior portions of the pharynx. It extends inferiorly from the oral pharynx and terminates in the esophagus at about the level of the VIth cervical vertebra. Its function is strictly digestive. The palato-pharangeal value is located in the region in which the respiratory and digestive tracts cross each other (pharyngeal Isthmus). Both in the act of swallowing and in speech, this value divide the pharynx into naso-pharyngeal and oro-pharyngeal cavities. The principal closure is affected by movement of the soft palate into contact with the posterior wall of the pharynx.

FOR AUTHOR USE ONLY

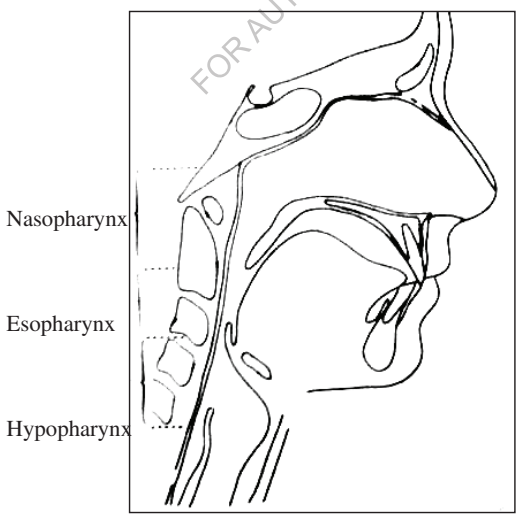


Fig. 5: Schematic picture of the different vales and articulators

3. PHYSIOLOGIC VALVE III:-

The Mouth:-The mouth is a complicated valve, capable of making many changes, both in capacity and in size of the orifices. It is modified by many articulators, the chief one being the tongue.

The three physiologic valves serve to form a number of more specific articulatory valves, such as:-

1. Mandibular lip against the maxillary lip.
2. Mandibular lip against the maxillary teeth.
3. Tip of the tongue against the alveolar ridge etc.

These valves are formed by momentary intrusions of some segment of the physiologic valves into the path of the outgoing stream.

FOR AUTHOR USE ONLY

ENGLISH CONSONANTS: THEIR POSITION AND MODE OF PRODUCTION

The production of English consonants and involve six valves below:-

1. Bilabial
2. labiodental
3. Linguodental
4. Lingeoalveolar
5. Linguopalatal
6. Linguovelar

Out of the above six valves five valves are affected by teeth position:-

I. **Bilabial Sounds: -** The sounds b, p and m are made by contact of the lips (as shown in Fig. 6). Insufficient support of lips by teeth and / or denture base can cause these sounds to be defective. Therefore, the anterior-posterior position of the anterior teeth and the thickness of the labial flange can affect the production of these sounds like wise an incorrect vertical dimension of occlusion (VDO) or teeth positioning hindering proper lip closure, might influence these sounds.

FOR AUTHOR USE ONLY

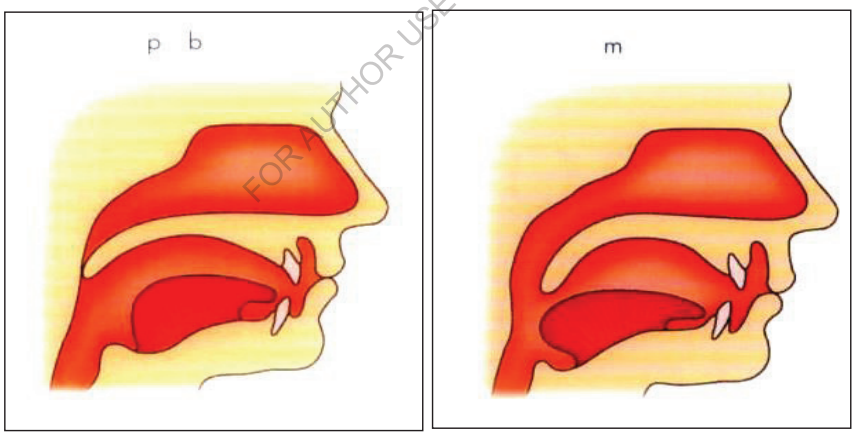

Fig. 6: Bilabial sounds

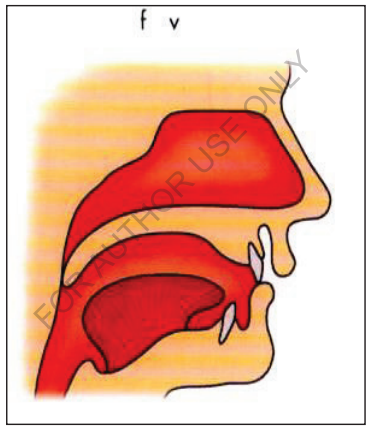
II. **Labio-dental Sounds: -** The labio-dental sounds f and v are made between the upper incisors and the labio-lingual center to the posterior third of the lower lip (as shown in Fig.7). If the upper anterior teeth are too short (set too high up), the V sound will be more like an 'f'. If they are too long (set too far down), the f

will sound more like a v. If upper teeth touch the labial side of the lower lip while these sounds are made, the upper teeth are too far back in the mouth. In this situation, the relationship of the inside of the lower lip to the labial surfaces of the teeth should be observed while the patient is speaking. If the lower lip drops away from the lower teeth during speech, the lower anterior teeth are most probably too far back in the mouth. If, on the other hand, imprints of the labial surfaces of the lower anterior teeth are made in the mucous membrane of the lower lip, or if the lower lip tends to raise the lower denture, the lower teeth are probably too far forward, and this means that the upper teeth are also too far forward.

If the upper anterior teeth are set too far back in the mouth, they will contact the lingual side of the lower lip when f and v sounds are made. This may also occur if the lower anterior teeth are too for forward in relation to the lower residual ridge.



FOR AUTHOR USE ONLY

Fig. 7: Labio-Dental sounds

III. Linguodental Sounds:-

Dental sounds (eg. Th) are made with the tip of the tongue extending slightly between the upper and lower anterior teeth (as shown in Fig. 8). This sound is actually made closer to the alveolus (the ridge) than to the tip of the teeth. Careful observation of the amount of tongue that can be seen with the words – this, that, these and those will provide information as to the labio-lingual position of te anterior teeth. If about 3mm of the tip of the tongue is not visible, the anterior teeth are probably too far forward, or there may be an excessive vertical overlap that does not allow sufficient space for the tongue to protrude between the anterior teeth. If more than

6mm of the tongue extends out between the teeth when such sounds are made, the teeth are probably too lingual.

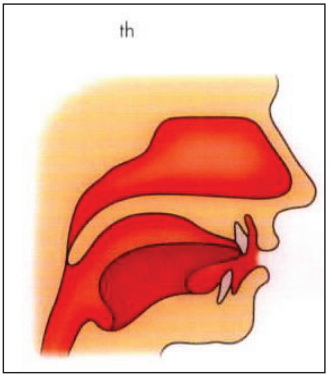


Fig. 8: Linguodental sounds

IV. Linguoalveolar Sounds:-

Alveolar sounds (eg. t, d, s, z, v & l) are made with the valve formed by contact of the tip of the tongue with the most anterior part of the palate (the alveolus) or the lingual sides of the anterior teeth (as shown in Fig. 9). The sibilants (sharp sounds) s, z, sh, ch & j (with ch & j being affricatives) are alveolar sounds, because the tongue and alveolus forms the controlling valve. The important observations when these sounds are produced are the relationship of the anterior teeth to each other. The upper and lower incisors should approach end to end but not touch. A phrase such as "I went to church to see the judge" will cause the patient to use these critical sounds, and the relative position of the incisal edges will provide a check on the total length of the upper and lower teeth (including their vertical overlap).

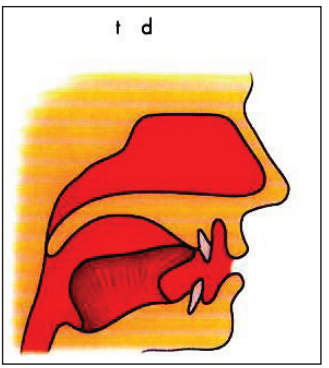

Fig. 9: Linguoalveolar sounds

THE 'S' SOUND

From a dental point of view, the S sound is the most interesting one. This is the case because its articulation is mainly influenced by the teeth and palatal part of the maxillary prosthesis (as shown in Fig. 10). Clinical experience suggests that s and t can cause most problems suggests that s and t can cause most problems in a prosthodontic context. In nearly all languages of the world, S is a common speech sound. The inter individual variation in articulatory details may be great due to individual variation in teeth, palate, lower jaw and tongue shape and size. However, the following phonetic properties are common to all s sounds.

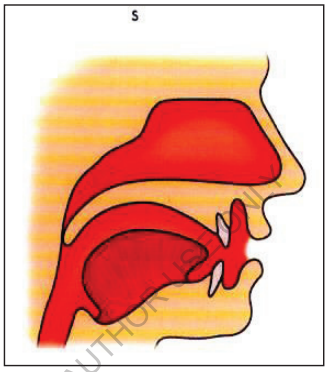

Fig. 10: 'S' sound

FOR AUTHOR USE ONLY

Linguopalatal and Articulatory characteristics :-

1. The tip of the tongue is placed far forward, coming but never touching the upper front incisors.
2. The sagittal groove is made in the upper front part of the tongue, with a small cross sectional area.
3. The tongue dorsum is flat.
4. Normally, the mandible will move forward and upward, with the teeth almost in contact.

Auditory characteristics

1. The sound is fairly loud, with a light, sibilant (sharp) quality.
   The S sound can be considered dental and alveolar speech sounds because they are produced equally well with too different tongue positions, but there can be some variations even behind the alveolus. Most people make the S sound with the tip of the tongue against the alveolus in the area of the rugae, but with a small space for air to escape between the tongue and alveolus. The tongue's anterior dorsum forms a narrow groove near the midline, with a cross section of about $10mm^2$. The size and shape of this small space will determine the quality of the sound. Part of the sibilant sound is generated when the teeth are being hit by a concentrated air jet. If the opening is too small, a whistle will result. If the space is too broad and thin, the S sound will be developed as sh, somewhat like a lisp. The frequent cause of undesired whistles with dentures is a posterior arch form that is too narrow.

Creation of a sharp s requires accuracy of the neuromuscular control system, for the creation of the groove and directioning of the air jet. Even small deviations of only 1mm will influence the quality. For example, if the tip of the tongue touches the upper front teeth, the result will a lisped sound.

FOR AUTHOR USE ONLY

V. Linguovelar sounds:-

The truly palatal sounds (example: year, she, insion and onion) present less of a problem for dentures. The velar sounds (k, g and ng) have no effect on dentures, except when the posterior palatal seal extension encroaches on the soft palate.

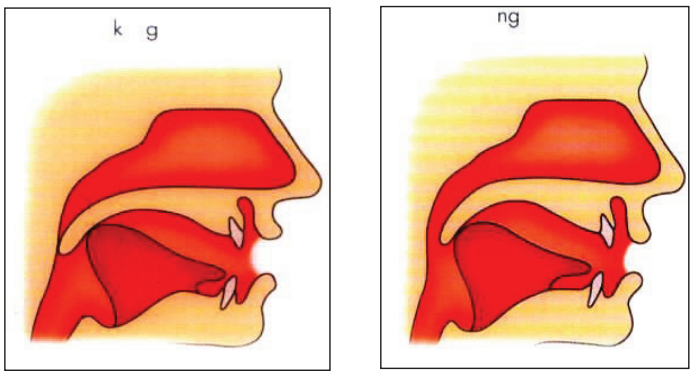

Fig. 11: Linguoalveolar sounds

VELOPHARYNGEAL FUNCTION

Hyper nasality and decreased intelligibility of speech may result from congenital or acquired defects of the velopharyngeal mechanism. Velopharyngeal deficits may result from congenital malformations (Such as cleft palate), developmental aberrations (Such as a short hard or soft palate, or deep nasopharynx), acquired neurological deficits, or the surgical resection of neoplastic disease.

CLASSIFICATION AND ETIOLOGY

Velopharyngeal deficiencies may be classified on the basis of physiology and/or structural integrity. Palatal insufficiency and palatal incompetence. Palatal insufficiency refers to patients with inadequate length of the hard and / or soft palate to affect velopharygeal closure, but with movement of the remaining tissues within normal physiological limits. The defect is secondary to a structural limitation. Patients with congenital and developmental aberrations and acquired soft palate defects would fall into this classification. Palatal incompetence refers to patients with essentially normal velopharyngeal structures, but the intact mechanism is unable to affect velopharyngeal closure. Patients with neurological diseases, such as bulbar poliomyelitis or myasthenia gravis, or neurologic deficits secondary to cerebrovascular accidents or closed head injuries are included in this category.

FOR AUTHOR USE ONLY

General Considerations

The velopharyngal mechanism is a precisely coordinated valve formed by several muscle groups. At rest, the soft palate drapes downward so that the oral pharynx and nasopharynx are open and coupled, allowing for normal breathing through the nasal passages. Classically, when velopharyngeal closure is required, the middle one third of the soft arcs upward and back ward to contact the posterior pharyngeal wall at or above the level of the palatal plane. The lateral pharyngeal walls move medially to contact the margins of the soft palate at or slightly below the level of the torus tubarius, and the posterior pharyngeal wall may move anteriorly to facilitate contact with the elevated soft palate. Complete, or nearly complete, velopharngeal closure is required for normal deglutition and the production of some speech sounds, such as plosives. For other phonemes, such as vowels and nasal consonants, the velopharyngeal port will be open in varying degrees.

Previous Methods of Evaluation

Aerodynamic and air flow studies, lateral and frontal plane radiographic analysis, spectrographic and coordination analyses, direct observation through large facial defects instrumentation for direct oral observation, video fluoroscopic and nasoendoscopic studies, more anatomical dissections, electromyographic analysis, and neurological innervation.

Current Methods of Evaluation

Many current studies have employed the use of multi view video fluoroscopy, nasal endoscopy and oral nasal airflow recording techniques to study the physiology of the velopharyngeal complex during speech and non speech functions. Several studies have combined more than one of these evaluation methods. These methodologies are unique in that the evaluation can be conducted with little or no impact upon the physiology of the region.

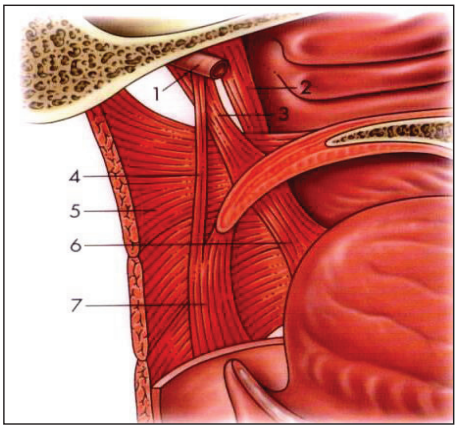
ANATOMY AND PHYSIOLOGY OF VELOPHARYNGEAL MECHANISM

The anatomy and physiology of the velopharyngeal mechanism will be described by dividing the description into the following anatomic components; namely, the soft palate, the posterior pharyngeal wall, and the lateral pharyngeal walls.



1 Auditory tube
2 Tensor veli palatini muscle
3 Levator veli palatini muscle
4 Salpingopharyngeus muscle
5 Superior constrictor muscle
6 Palatoglossus muscle
7 Palatopharyngeus muscle

SOFT PALATE

Position and Movement

The position and movement of the soft palate, in relation to the pharynx, changes with age. At birth and shortly thereafter, the soft palate at rest is roughly parallel to the roof of the pharynx so that the upper nasopharynx is only a narrow slot. Closure of the velopharyngeal mechanism is accomplished by essentially a superior inferior movement of the soft palate. As growth occurs in the pharyngeal area, and as the adenoidal tissues regress, the movement of the soft palate takes on the characteristic anterior posterior elevation displayed by most adults.

Velopharyngeal closure is slightly below the level of the palatal plane up to 8 years of age, and is consistently above the level of the palatal plane thereafter.

The extent of the closure of the soft palate with the posterior pharyngeal wall varies with head position. An extended head position results in a deeper nasopharynx

than when the head is held in the Frankfort plane. **McWilliams(1969)**, in a radiographic study of 101 children with repaired cleft palates, found with the posterior pharyngeal wall was reduced significantly when the head was in an extended position.

The pattern of soft palate movement varies between men or women. This study disclosed that the soft palate was longer, the elevation was greater, the amount of contact with the posterior pharyngeal was less, and the inferior point of contact with the posterior pharyngeal wall was consistently higher in men than in women.

Velar Eminence and Musculus Uvulae

While the entire soft palate increases in length during closure, the posterior two thirds demonstrates a greater degree of lengthening and significant thickening. Several investigators noted a central longitudinal thickening or elevation of the nasal surface of the soft palate that was termed the velar eminence.

The musculus uvulas are responsible for the velar eminence, which contribute to velar stretch, and is essential for normal velo-pharyngeal closure. This paired muscle is the only intrinsic muscle of the soft palate.

Each of the 2 bundles of the musculus uvulae has its origin from the tendinous palatal aponeurosis, which is posterior to the hard palate and anterior to the insertion of the levator veli palatini muscle. The bundles converge above and at right angles to the sling of the levator veli palatini, and redivide and insert into the basement membrane and connective tissue of the uvula. The bulk of uvula consists of glandular tissue interspersed with muscle fibers.

FOR AUTHOR USE ONLY

The levator supplies the force with contraction and elevates the soft palate. At the same time, the musculus uvulae contrast to fill the central gap between the soft palate, the lateral pharyngeal walls, and the posterior pharyngeal wall along the central one third of the nasal surface of the soft palate. The contraction of the musculus uvulae is considered essential for those individuals having any circular pattern of closure.

While the entire soft palate increases in length during closure, the central and posterior portions demonstrate a proportionally greater degree of lengthening along with thickening. This lengthening during closure has been termed velar stretch. The amount of velar stretch seems related to the task and/or anatomical or functional variables associated with the structures involved in closure.

Levator Veli Palatini and Other Muscles

Levator Veli Palatini muscles is responsible for palatal elevation. While the levator veli palatini muscles supply the force for palatal elevation, the finite positioning of the soft palate may be under the control of several other muscles acting in a reciprocal manner with the levator.

A consistent interaction was observed between the levator, the palatoglossus, and the palatopharyngeus. If the levator contracted forcefully, the palatoglossus and the palatopharyngeus also contracted forcefully. The reverse scenario was also true. The palatoglossus and the palatopharyngeus create a downward pull to the soft palate and oppose the upward contraction of the levator. Therefore, the levator must contract of the levator. Therefore, the levator must contract more forcefully if the palatoglossus and / or palatopharyngeus contact forcefully. The important function of the palatoglossus and palatopharyngeus in speech is to aid in positioning the tongue and pharynx. If the palatoglossus contracts to aid in tongue elevation and / or the palatopharyngeus contracts to restrict the pharynx, the levator veli palatini must increase its contraction force proportionally to achieve the desired velar elevation. Thus, there is a reciprocal relationship between the 3 muscles in positioning the soft palate and the tongue.

FOR AUTHOR USE ONLY

Since the most superior constrictor needs further investigation. Since the most superior fibers of the superior constrictor insert into the soft palate, Kuehn speculated that these muscle fibers may assist the muscular uvulae to draw or stretch the velum posteriorly.

These reciprocal muscular relationships help to explain the inter relationship between tongue position (or velopharyngeal closure) and speech. Tongue posture and movement may differ with velopharyngeal incompetence or insufficiency. These patients often have a more posterior and superior tongue position during speech. Warren felt that a high tongue carriage would increase vocal tract resistance for patients with a velopharyngeal deficiency. These investigators felt that this compensatory tongue posture assisted with soft palate elevation, but also contributed to the faulty articulation reported for these patients.

Posterior Pharyngeal Wall

In 1863 and 1869, Gustof Passavant described a horizontal “cross roll” on the posterior pharyngeal wall which occurred during speech and swallowing in cleft

palate patients. This forward bulging, corresponding to the level of the atlas, has been termed Passavant's ridge or pad. This cross roll may vary from a slight forward bulging of the posterior pharyngeal wall to a very distinct roll extending horizontally across the posterior pharyngeal wall to blend with the mediolateral movement of the lateral pharyngeal walls. In its prominent form, Passavant's pad may extend forward and superiorly as much as 5mm in both directions. Passavant's ridge serves as a guide for proper placement of the soft palate obturator prosthesis.

To what extent does Passavant's ridge contribute to velopharyngeal closure?. This point is debatable. Calnan reported that Passavant's ridge varied in location, tended to be located below the level of palatal closure, contracted slowly and in an uncoordinated manner, and tended to fatigue easily. He concluded that it contributed little to velopharyngeal closure.

What muscules are responsible for posterior pharyngeal wall movement? This point, also, is debatable. The lateral and posterior walls of the oropharynx and nasopharynx are composed of muscle fibers of the fan-shaped superior constrictor muscle. The superior constrictor muscle has its origin along the pterygomandibular raphae and the tuberosity of the maxilla, and its fibers course posteriorly and horizontally to insert and anastomose with its counterpart into the aponeurosis in the midline of the posterior pharyngeal wall of both the oropharynx and nasopharynx. The anatomical components of Passavant's ridge have been debated, since fibers of the pharyngopalatinus muscle were found to intermingle with those of the superior constrictor. Calnan speculated that it was the pharyngopalatinus that comprised Passavant's ridge. Others believe that fibers of the superior constrictor form this unusual configuration, and they are responsible for the anterior movement displayed by the posterior pharyngeal wall.

FOR AUTHOR USE ONLY

The lateral Pharyngeal walls

Lateral pharyngeal wall movement is essential if normal speech is to be achieved with either prosthetic obturation or surgical reconstruction. Lateral pharyngeal wall motion is difficult to assess because the drape of the soft palate precludes direct oral observation, and lateral radiographic projections will not disclose lateral pharyngeal wall motion unless the head is extended posteriorly with the patients in a supine position.

Lateral pharyngeal wall motion requires different methods of evaluation. Beumer observed and photographed the velo-pharngeal mechanism of 2 patients through large facial defects. He traced lateral wall movements during speech and

swallowing from motion picture films and concluded that lateral wall movements were an essential component of closure.

Following placement of an obturator, or a pharyngeal flap procedure, the adjacent pharyngeal tissues demonstrate increased motion. The physiologic basis for this phenomenon has not been explained completely.

Other forms of stimulation of the velo-pharngeal mechanism, such as muscle exercises, speech therapy and electrical stimulation, have not been effective in demonstrating a sustained increase in pharyngeal movements leading to improved speech.

The muscles contributing to the movement of the lateral pharyngeal walls, the direction of lateral wall movement, and the level laterally of velo-pharyngeal closure remain points of contention. The levator veli palatini muscle has its origin lateral to the torus tubarius, without attachment to the Eustachian tube. The levator courses downward, forward, and medially, and inserts into the central one third of the soft palate.

It appears that the palato-pharyngeus contributes little to the medial and posterior movement of the lateral pharyngeal walls. Its primary function is to mobilize the larynx and narrow the pharynx in speech and swallowing. Dickson felt that, in the adult, the fibers of the palato-pharyngeus are so intertwined with the superior constrictor that analysis of the function and boundaries of the palato-pharyngeus are difficult to delineate.

FOR AUTHOR USE ONLY

THE TONGUE

The tongue is the principle articulator for speech, and learning its position for a given sound is the key to speech learning. To divide its role in speech the dorsum of the tongue is divided into a back portion, which approximates the soft palate, and a front portion, which approximates the hard palate, and the sides are referred its as the tongue blade and the apex is called the tongue tip, or apex.

To pronounce ‘a’ the dorsum of the tongue is arched and the blade contacting the alveolar ridge and the tip resting behind the lower incisors. The position for ‘e’ is essentially the same, except the dorsum is arched a little higher, with the blade in heavier contact with the alveolar ridge and the tip raised slightly. To pronounce ‘i’, the tongue is pulled back with the dorsum flattened at the beginning of the sound, but raises to the ‘e’ position for the completion. To pronounce ‘U’ the tongue first assumes the ‘e’ position then fills back with the dorsum flattened for the second part of the sound. For the ‘o’ tongue is in its flattest and lowest position with no palatal contact.

Functional Tongue Classification

The working range of the mobile tongue varies with the individual. Therefore, classification and knowledge of the conditions that cause variations are indicated.

The degree of activity and the variation in functional type suggest the following classification:-

1. The occupational tongue.
2. The still tongue
3. The normal tongue
4. The habitual tongue.

The term "*occupational tongue*" was selected to apply to those people whose activities require increased tongue action. This includes jurists, teachers, lecturers and preachers.
The developed increased muscular positioning force will herein after be designated "tongue power movements".

FOR AUTHOR USE ONLY

The "*still tongue*" is at the opposite end of the classification. In these patients, as a result of limited activity, due to injury, deformity, or undue timidity, a passive tongue exists. A example is ankyloglossia.

The "*normal tongue*" exists between these two extreme ranges and refers to the type of tongue function in people exhibiting a normal or average development. These cases are welcomed by the prosthodontist, as they give a range within limits in effecting desirable rehabilitation.

Tooth alignment should be effected without encroachment upon the tongue functioning space. The base of the tongue is frequently "hooked" by the lower second molars. This factor is a cause of unstable lower dentures which warrants recognition. Positioning lower second molars in complete dentures should be arranged without tongue impingement. In some cases, the insertion of a fixed appliance or removable partial denture will cause immediate tongue laceration of varying degrees. The traumatic problem in occupational tongues has a favorable prognosis with early recognition and adequate adjustment to the problem. Observation confirms the fact that tongue laceration rarely results from functional tongue interference in complete dentures, for the power movement of the tongue is capable of dislodging the interfering dentures, and thereby escaping injury. The value in straddling interference of flange margins upon the tongue is in effecting better

denture stability in function. The reaction of the tongue to interference with power thrusts by removable partial dentures or fixed bridges presents a different picture. The inability of the tongue to escape or dislodge the appliances results in repeated irritation or trauma. The degree of injury is commensurable with the duration of time and the intensity of the interference.

The "*habitual tongue*" is the term chosen to describe those disturbing power movements developed by habit, exclusive of the arching of the tongue to help retain dentures as described by Rowe". The base of the tongue is thick and powerful, and the dislodging force is most offending to prosthetic dentures. It is suggested that the lower second molar in prosthesis may be reduced bucco-lingually, and may be set buccal to the ridge crest to negate the objectionable effects of classic accepted tooth position that frequently tend to defeat lower denture stability. When narrowing of the last lower molars in complete dentures fails to give sufficient functional tongue space, it is advisable to set to combined opposing last molars in buccal version, reducing the lingual surface linguo-buccally, in distal progression. It is also possible to increase tongue space for better function by placing the last molars in a cross bite relation. The employment of a cross bite to effect greater tongue space is a new use for this method. In extreme cases, the second molars can be eliminated completely.

FOR AUTHOR USE ONLY

THE MANDIBULAR MOVEMENT OF SPEECH AND THEIR SEVEN RELATED VALUES

Dentist's worries about where to position the six lower anterior teeth can be greatly minimized because patients, when speaking, tell this in a symphony of mandibular movement rather than in vocal words.

By recording and interpreting certain mandibular movements of speech, the patient reveals seven informative facts that are directly related to restoring the original mandibular tooth position, phonetic sharpness, and occlusal harmony.

These are:-

1. The vertical overlap.
2. Horizontal overlap,
3. Former lower anterior tooth display,
4. Former class of occlusion.
5. Maximum usable vertical dimension.
6. An accurate index for incisal guidance and
7. The maximum serviceable cusp height.

FOR AUTHOR USE ONLY

Which mandibular movement to record?

The degrees of movement and the intimacy of teeth to one another during speech vary considerably, and this variation is dependent upon the speed and volume of the desired speech effects. However, two conditions always exist during speech. The first is that the lower teeth must move downward out of their centric occlusal position. This movement must be sufficient to prevent any tooth contacts during speech. Second, when repeatedly pronouncing the letter "S", the mandible assumes its most forward speaking position, and the anterior teeth are in their most intimate relation with one another. At this time, the incisal edges of the lower teeth, with a space of about 1.0 mm, between them. In a fair percentage of patients, however, there is practically no forward movement of the mandible and this fact is just as important and informative as any measurable movement.

To record any directional movement, there must be at least two control points. The centric occlusal relation is one control and the "S" position is used for the other. By setting the incisal edges of the lower teeth to this functional "S" relationship, a recording is automatically made of the extent of the downward and

forward movements from centric occlusal position. With some, these movements are great , with others they are surprisingly small. It is the extent of these movements, indicated by the difference between the "S" position and their position in centric occlusion that is the key to these seven values.

Improved phonetics in denture construction:-

The literature in dental prosthetics was reviewed and previous methods for improving phonetics were evaluated.

1. **Snow,** after observing many casts of natural dentitions, pointed out that a tracing which started t the vault and passed over the lingual alveolar area to the incisal edge of the maxillary incisor always formed a reverse curve. He recommend thickening and contouring the area lingual to the collars of the maxillary incisors of the denture in order to reproduce this reverse curve, and he maintained that this reproduction facilitated the pronunciation of S and SH.
2. **Landa** uses the labio dental sounds (F and V) as an adjunct to the arrangement of the maxillay anterior teeth. He believes the teeth should be arranged so that these fricatives can be pronounced easily and naturally. Landa also maintains that proper vertical dimension is the key to proper pronunciation of S and SH.
3. **Sears** reports that clearer S pronunciation will result from fashioning the area of the anterior median ridge according to the type of tongue. He recommends making a groove in this area for the broad tongue with a slight median sulcus and the building of a ridge in this area for the tongue with a deep median sulcus. Sears also advocates making a palatogram on patients whose median sulcus of the tongue does not coincide with the midline.
4. **Pound** believes that the entire lingual aspect of the maxillary denture should be contoured to simulate the normal palate, if proper phonetics is to be attained. The tongue plays a major role in speech. It changes position and shape for the pronunciation of each of the vowels, and it is the principal articulator for the consonants. In pronouncing the consonants, the tongue contacts various portions of the teeth, the alveolar ridge, and the hard palate. Since these structures are either replaced or covered by the denture, it was basic to the study to know exactly which portions of these structures are normally contacted by the tongue in pronouncing a given consonant. To accomplish this, palatograms were made to incorporate a maximum variety of tooth arrangement, tooth occlusion, arch form arch size, vault form, and vault depth.

FOR AUTHOR USE ONLY

5. The area most sensitive to thickness is the anterior alveolar area from cuspid to cuspid. An addition of 1 mm, thickness in this area made speech awkward and indistinct, and an additional 1 mm thickness in the posterior alveolar area made speech awkward but not indistinct. The entire vault area could be thickened up to the tongue palatal tracing line without interfering with speech.

The speaking method in measuring vertical dimension:-

The exact measurement of the natural vertical dimension is most essential in the successful practice of many phases of dentistry. It has been found that the greatest cause of full denture difficulties is the failure to duplicate the normal vertical dimension. In occlusal reconstruction, many fine dentists have found, through experience that increasing the vertical dimension for patients with supposedly shortened vertical dimension ended in failure.

6. Also it is proved scientifically by the speaking method that vertical dimensional must not be increased. Those dentists who reconstruct the occlusion of patients will generally find that failures can be avoided by completing the treatment without the increase of vertical dimension. If this dimension should be increased, this treatment must be based on scientific proof and not on the opinion of the operator.

FOR AUTHOR USE ONLY

The Speaking Method

The patient is seated in an upright position without the use of the headrest, with the eyes forward, and the occlusal surface of the upper posterior teeth parallel to the floor. The measurement is taken under identical conditions of posture and vigor of speech. The head must not tilt forward or backward and the patient should speak rapidly in a calm and relaxed manner. A particular observation must be made that the patient does not consciously control the movement of the mandible, as any variation from normal might affect the measurements.

Direct the patient to close into centric occlusion, with the upper and lower teeth together in maximum occlusal contact. Draw the centric occlusion line with sharp pencil on a lower anterior tooth at the horizontal level of the incisal edge of the opposing upper anterior tooth.

Have the patient say “yes” and while the phonetic sound s is being pronounced, draw the closest speaking line on the same lower anterior tooth at the horizontal level of the upper incisal edge. The distance between the centric occlusion line (lower line)

and the closest speaking line (upper line) is called the closest speaking space. This closest speaking space is the measurement for vertical dimension.

In some patients, the mandible will move forward during the pronunciation of some or all speech sounds. This forward movement will not affect the accuracy of the measurement because the same movement occurs, and the vertical distance between the lines in always remeasured in the same manner with both natural and artificial teeth.

8. The closest speaking space may vary in different. In the series of patients examined, the measurements ranged from 0 to 10 mm, which proves that there is no such thing as "an average" in measuring vertical dimension. Measurement must be made with accuracy as it has been found that increasing the vertical dimension only one millimeter will cause discomfort to the patient

9. The closest speaking space has been found to be constant in each individual. It is felt that the closest speaking space should be constant throughout life. This belief may be accounted for by the "all or none law" of muscle physiology which states that each muscle fiber is in maximum contraction during the stimulus of function. Because this system of measuring vertical dimension is based on physiologic function of muscles while used in speaking under similar conditions, the same level of the mandible are caused by maximum function of the specific muscle fibers involved.

Out of the 44 phonetic sounds of the English language, one or more of the six sibilants s, z, sh, ch, and j in such words as yes, buss, fish, measure, church and judge are the sounds which cause the closest level of the mandible to the maxilla while speaking. In the exceptional cases where other sounds caused the closest level, it was found that the sibilants caused a constant and accurate level of the mandible in relation to the maxilla. The remaining of the 44 phonetic sounds caused wider spaces between the mandible and the maxilla. That was neither constant nor accurate and could not be relied upon as a guide to the measurement of vertical dimension. The closest speaking space as measured in the natural dentition must be reproduced in full dentures after the loss of the remaining natural teeth.

It is always advisable to measure the closest speaking space of all full denture patients at least once a year until it is found that there is an end to discomfort and perhaps to alveolar shrinkage or wear of the artificial teeth. If the closest speaking space remains constant in the full dentures, it is simple to duplicate this same vertical dimension when registering the maxillo-mandibular relation of new dentures, with the additional help of tattoo dots on the alveolar ridges.

FOR PUNJAB USE ONLY

The closest speaking space to measure the vertical dimension in this speaking method must not be confused with free way space of the centric relation method. The free way space establishes vertical dimension when the muscles involved are at complete rest, and the mandible is in its rest position. The closest speaking space measures vertical dimension when the mandible and muscles involved are in the active full function of speech.

STUTTERING (STAMMERING)

Definition:-

Stammering is a disorder of the rhythm of speech in which the speaker knows precisely what he wishes to say but cannot for the moment say it, because of involuntary repetitions, prolongations, or cessation of sounds **(World Health Organization, 1978**). It is more than just a disruption in the smooth flow of words, as the syndrome is typically characterized by emotional reactions to the trouble experienced in speaking. Therefore it should be viewed as a disorder of communication rather than purely a speech symptom. If it persists into adolescence or adulthood it frequently becomes a major obstacle to the formation of close relationship and careers.

FOR AUTHOR USE ONLY

Onset:-

Stammering is a disorder of childhood often occurring between the ages of 2 or 10 years, but more commonly between 2 and 5 years (Blood stein, 1960). It is at exactly this time when non fluency may be observed as a normal stage in language development. The child has ideas which he wishes to communicate, but his expressive language has not developed sufficiently to allow him to do so and therefore there are hesitancies as he plans his utterances. It is vital that a differential diagnosis between normal non fluency and the onset of stammering is made, to prevent the development of a chronic handicap.

Normal non-fluency consists mainly to whole word or phrase repetitions (for example it's ……. It's …… cold today or put the ….. put the …. Ball there), interjections, and revisions (the man…. The boy is happy) with occasional part word repetitions. The stammering child is characterized by an increase in part word repetitions (bbbbbbball), sound prolongation (b…. ball) and the insertion of the schwa vowel after the initial sound (tu-tu-tu-today). Sometimes the child may be seen to struggle to get the word out, disrupting the expiratory airflow. Variations of

the pitch, intensity and rate of the voice may be observed. Concomitant movements of the head and trunk and word and situation avoidance may develop.
Part of the reason that this disorder is so complex, is due to its variability in severity and frequency with time and circumstance.

Aetiology :-

Many theories as to aetiology have been proposed from organic, psychogenic to viewing stammering as a learned behaviour. Despite much research, however, the aetiology is still not fully understood. It is known, however, that there is often a familial pattern. The risk of stammering among first degree relatives exceeds the population risk by a factor of three, and this risk is increased for the offspring of female stammerers. It is quite probably that environmental factors do play a part in the development and maintenance of the syndrome, and that possibly the psychogenic aspects, in particular difficulties with social adjustment, develop as a learned reaction to the handicap. Stammerers often demonstrate poor interpersonal skills, avoid social contact, and do not initiate communication.

Current research is studying neurophysiological theory on the supposition that there is a neurological inadequacy.

FOR AUTHOR USE ONLY

Incidence:-

In childhood, the prevalence in the prepubertal population is 1% dropping to 0.8% at 16years of age. The distribution of stammerers between males and females is three to one. This disproportion increases with age, and the remission of stammering is more common in girls than boys. This has been attributed to differences in constitution, in particular physical maturation and speech and language development, and to the different parental attitudes and expectations of boys and girls (**Andrews *et al.* 1983**.)

Management:-

The speech therapist's assessment of stammering is complex. A quantitative and qualitative assessment of the overt behavioural manifestations of dysfluency is made. Other aspects of speech and language behaviour are assessed and information on education achievements sought. Environmental factors including the child's and parent's attitudes, and other significant persons, are all carefully explored.

Current approaches to therapy can take widely different forms, and is determined by the assessment. Treatment usually is based on three main principles:-

1. Modification of the environmental factors that are contributing to the development and maintenance of stammering may be indicated.
2. Therapy may be needed to modify directly aspects of speech production, with attention to the effective carryover and maintenance of fluency .
3. The importance of changing the child's perception of himself as a stammerer, sometimes needs to be worked upon in therapy.

PROSTHODONTIC CONSIDERATIONS AND REHABILITATION OF SPEECH

- Speech problems are usually identified immediately following phonetic treatment.
- After denture insertion, it is some times difficult to receive speech habits immediately, but gradual process of retaining tongue positions good compensation can be achieved in later periods.
- Speech adaptation to new complete dentures normally takes place within 2-4 weeks after insertion.
- During fabrication of denture, certain guidelines have to be followed in order to achieve clarity of speech.

1) <u>Effect of denture thickness and peripheral outlines</u>

1) If the thickness of the denture base covering the palatal area is more, then lipsing of the sounds will occur.

   Allen (1958) found that an additional thickness of 1mm in the anterior palatal area made speech awakward and indistinct.

2) The denture base thickness in the postdam area will irritate the dorsum of the tongue which will impede the speech and there is a possibility in producing feeling of nausea and denture may be unseated during sounds, which requires sudden repositioning of the tongue to control and stabilize it.

   The upper denture base in posterior region must be kept thin and the posterior border should be merge with soft tissues.

3) If the lingual flange of the lower denture is too thick in the anterior region, will encroach the space needed by the tongue and this results in faulty production of ‘s’ sound.

It can be corrected by arranging the artificial teeth, in same position as the natural teeth will occupy and shaping the lingual flange so that there will be enough tongue space to establish.

FOR AUTHOR USE ONLY

2) Effect of tooth position on speech

If the lower anterior teeth are arranged too lingually, the tongue is forced to arch itself upto a higher position and the airway is to be too small and there will be faulty pronunciation in 's' and 'z' sounds.

If upper anteriors are too short of occlusal plane the word 'v' will more likely pronounce as 'f'. If upper anteriors are arranged below the occlusal plane the word 'f' will be pronounced like 'v'.

The labiodental sounds like 'f', 'v' are helpful in determining the anteroposterior positioning of the upper incisors and the occlusal plane.

3) Effect of dental arch form on speech:

If the arch is narrow, which will crample the tongue which affects the size and shape of the air channel results in faulty articulation of the consonants like 't, d, l, n, s, t' where lateral margins of the tongue makes contact with palatal surfaces of the upper posterior teeth.

The correction can be done by the slight thickening of the denture base in the center of the palate, so that tongue doesnot have to extend up as far as into narrow palatal vault.

FOR AUTHOR USE ONLY

4) Effect of vertical dimension on speech:

Fymbo (1936) pointed out that defective speech is most frequently associated with increased vertical dimension which may result in difficulty in pronouncing sounds like 'b, m, p, f, v'.

Landa (1947) recommended various phonetic tests to determine proper vertical dimension using sounds such as 's, c, z'.

Silverman (1956) stated that sibilient sound 's' as a mean for determining the correct vertical dimension. He established the "closest speaking space" and used this as clearance area between the dentures.

The bilabial sounds like 'm' is helpful in determining the vertical dimension, when this sound is pronounced there will be passive contact between the upper and the lower lip, which aid in obtaining the correct vertical dimension.

5) Whistle and Swish sounds:

Silverman (1967) stated that the Whistle and Swish sounds are produced during speech due to air abnormally passing over the tongue and through the interincisal space. These sounds may be caused due to decreased overjet.

6) Effect of denture esthetics on speech:

Speech is some times related to patients emotional attitudes towards the denture esthetics.

Lawson (1973) stated that when there is any change in patient mouth, then there will be anxiety reaction will occur some patients dissatisfied with their teeth appearance in denture and to overcome this problem they shows abnormal movement of lip, jaws, and tongue during speech.

CLEFT PALATE

A failure of fusion of the two halves of the palate during the embryological period; between the sixth and ninth week after conception is manifested as the cleft of the upper lip, upper gum ridge, the hard palate, the soft palate, or the combinations of the above. The clefts may be complete or incomplete, i.e. in some cases there was no fusion of the two halves of the structures and in other cases, the fusion had started but was disrupted before the structure was complete.

Fig. 15: Cleft involving hard & Soft palate

The oral cleft team:-

The essential ingredients of a successful oral cleft team include the freedom for all professionals to give their points of view:-

- The **plastic surgeon** specializes is the modification of soft tissues.
- The **oro-laryoglogist** (ENT specialist), he will evaluate and treat tonsils and adenoids and will perform ear surgery, if indicated.
- The **orthodontist** helps in positioning of the teeth.

- **Prosthodontists** designs and builds prosthesis for the oral cleft client. These may include speech bulbs, palatal lifts, and obturators.
- **Pediatrician** oversees the general health of the child.
- **Audiologist** administers and interprets the routine hearing tests.
- **Speech pathologists** seek to improve the patient's speech.

Surgery for clefts:-

Primary surgery for the cleft is done early in child's life with major considerations given to impious the child's facial appearance. Secondary surgery on the palate usually involves some attempt to improve the speech of the client some of the procedures are designed to move the palate backwards. More popular are the attempts to bring the back wall of the throat forward.

Prosthesis:-

There are certain cases of cleft palate for whom surgery is not the wisest course. Certain clefts are so large or the tissue remaining so scant that the prognosis for good speech, easy swallowing and a good facial appearance is very poor. Essentially prosthesis are artificial substitutes for missing or deficient parts.

FOR AUTHOR USE ONLY

Types of Prosthesis:-

The dental portion of prosthesis may be designed to improve the cosmetic appearance as well as to improve speech. The portion of the appliance that is designed to plug or block the opening in an unrepaired palatal cleft is referred to as an obturator.

Velopharyngeal closure can be brought about by the speech bulb designed by prosthodontist. This prosthesis extends from the palatal portion into the nasopharynx to fill the deficient velopharangeal space. It is used to decrease the hypernasality when the surgery is contra indicated. A palatal left is designed to elevate the middle section of velum and is used in cases in which there is little evidence of enough muscular potential for velopharyngeal closure, even though the palate seems long enough.

A palatal stimulator provides mechanical resistance to the normal movement of the velum so that the client strengthen the weak muscles in the velopharyngeal area.

PROSTHODONTIC REHABILITATION

Obturator is derived from the Latin verb, Obturare, which means “to close” or “to shut off”. This definition provides an appropriate description of the objective of obturation in patients with velopharyngeal incompetence or insufficiency. A prosthesis placed following resection of portions of the bony maxillae and adjacent structures is basically a covering prosthesis to reestablish the oral- nasal partition. The extension superiorly of the obturator into the defect provides the basis for improved retention, stability, and support for the prosthesis. There is very little movement of the tissues bordering these defects. In contrast, obturators constructed for patients with soft palate defects must function in concert with peripheral tissues displaying considerable movement.

Obturator prostheses fabricated for patients with velopharyngeal deficits vary with the location and nature of the defect or deficiency.

FOR AUTHOR USE ONLY

Since most resections included adjacent structures, the delicate functional balance of the velopharyngeal mechanism will also be affected to varying degrees, depending on the extent of the initial resection and the method of surgical defects are lined and /or closed primarily with various types of flaps or a skin graft. Therefore, the prosthodontist may be asked to restore a velopharyngeal defect which may, in part, be nonfunctional. If the soft tissues peripheral to the defect do not display some movement, rarely will speech be normal with either a prosthetic obturator prosthesis or surgical reconstruction. Movement of the lateral and posterior walls and movement of the residual soft palate are essential for either method of rehabilitation.

Immediate and Delayed Surgical Obturation:-

If resection of the portions of the velopharyngeal mechanism is contemplated for control of neoplastic disease, the placement of an immediate or delayed surgical obturator may be indicated. Immediate surgical obturation is most useful in dentulous patients, where the entire soft palate is to be resected. In the edentulous patients, or with patients with limited medial or lateral posterior border resections, delayed obturation may be the treatment of choice. The principle advantage of immediate

surgical obturators for soft palate defects is support and retention of the surgical packing.

Immediate Surgical Obturation :-

Immediate surgical obturators, constructed presurgically, are approximations with regard to the level of placement and the contours of the lateral and posterior margins. The guesswork can be minimized if an extended impression of the soft palate is obtained.

After the cast is retrieved, it is altered to correspond to the proposed defect. The superior- inferior level of the obturator is determined by the plane of the hard palate. The cast is altered to extend the palatal plane to within 2 to3 mm of the estimated position of the posterior pharyngeal wall. The width of the obturator is determined by the width of the soft palate. These guidelines will usually produce a prosthesis that will not be overextended. Adjustments at surgery may be necessary to avoid excessive tissue contact or to provide space for a nasogastric tube. Adaptation during the immediate postoperative period need not be precise, as the surgical packing will correct minor discrepancies. In addition, some patients will have a tracheostomy tube placed at surgery, so speech will be compromised during the immediate postsurgical period.

FOR AUTHOR USE ONLY

Approximately 7 to 10 days postsurgically, the prosthesis is removed along with the surgical packing. The lateral and posterior margins of the prosthesis are checked for tissue contact. Appropriate corrections are made and tissue treatment material is added to the lateral margins of the prosthesis. The patient is instructed to perform head and swallowing movements to activate the velopharyngeal complex and mold the lining material. Often, patients are reluctant to activate the remaining velopharyngeal musculature initially because of discomfort, edema, and possible neurologic deficits. Hence, speech in the immediate postoperative period can be muffled, as lateral pharyngeal wall movements are necessary to control nasal emissions and establish proper resonance balance. As healing progresses and the peripheral tissues display a greater range of movement, trimming and reapplication of a suitable liner will be necessary. As the edema abates and movement of these tissues increases, speech will also improve. The patient is monitored with sequential appointments until the definitive prosthesis can be constructed.

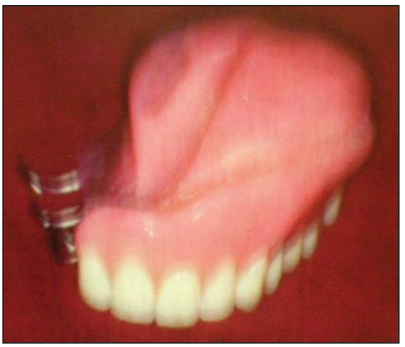

Fig. 16: Immediate obturator

Delayed Surgical Obturation:-

Patients with smaller defects of the posterior or lateral border of the soft palate often are best served with delayed surgical obturation. If the defect is limited, the postsurgical edema will tend to mask the velopharyngeal defect during the initial postsurgical period. As healing progresses, the patient can be considered for a delayed surgical prosthesis .In edentulous or partially edentulous patients, consideration should be given to attaching the delayed surgical obturator to the existing maxillary complete or partial denture.

FOR AUTHOR USE ONLY

Definitive Obturation:-

Patients exhibiting considerable movement of the residual velopharyngeal complex during function have an excellent prognosis for achieving normal speech with prosthesis. Movement of the lateral pharyngeal walls is essential for control of nasal emission.

The obturator is attached to a conventional prosthesis. If the patient is dentulous, a removable partial denture framework retains the obturator. The obturator should be rigid. Therefore, it does not attempt to duplicate the movements of the soft palate. It is a fixed platform of acrylic resin which provides surface contact for the remaining musculature of the velopharyngeal mechanism during function. If the lateral and posterior pharyngeal walls exhibit normal movement, a space will exist between these structures and the obturator when these tissues are at rest. The surrounding space permits breathing through the nasal cavity and the production of nasal consonant phonemes.

The level of optimal obturator placement in the nasopharynx is determined by the position of movement of the residual velopharyngeal mechanism. Passavant's ridge and the anterior tubercle of the atlas can vary in location in relation to normal velopharyngeal closure. Therefore, definite landmarks regarding obturator placement are some that difficult to delineate. As a general rule, the prosthodontist should consider the following guidelines for location of the obturator segment of the prosthesis:-

1. The obturator for an adult patient should be located in the nasopharynx at the level of normal velopharyngeal closure.
2. The inferior margin of the obturator should not extend below the lower level of muscular activity exhibited by the residual velopharyngeal complex.
3. The superior margin of the obturator should not extend above the level of muscular activity.
4. The inferior extension of the obturator will usually be an extension of the palate plane, and extended to the posterior pharyngeal wall.

FOR AUTHOR USE ONLY

Fig. 17: Showing Permanent obturator

Speech evaluation following obturator placement:-

The prosthodontist may require the assistance of a speech pathologist to evaluate articulation errors and inappropriate oral-nasal resonance balance. Cleft palate patients will invariably require speech therapy in order to utilize their obturator prosthesis more effectively, whereas patients with obturators for acquired defects of the soft palate usually do not need this retraining. The articulation test or the Iowa

Pressure Articulation Test can be administered by the prosthodontist, but definitive judgments concerning articulatory deficience should be reserved for the speech pathologist. Patients with hypernasality often exhibit facial grimaces to partially occlude the nostrils and the nasal valve, or abnormal tongue postures as a compensatory adjustment to reduce nasal emission.

The obturator is adjusted to the point where the patient can produce a clear "p" and a sustained "f" or "s" sound without emission of air through the nose, as well as understandable nasal consonarit sounds, such as "m". Several authors suggested that the sustained pressure required for the "s" phoneme may be a reliable method of evaluating the effectiveness of the obturator. Whereas greater intraoral pressure may be required for stop-plosives, such as "p", the sustained pressure required for stop-plosives, such as "p", the sustained pressure required for "s" mitigates the compensatory elevation of the tongue to assist with closure. The tests discussed previously, such as multiview videofuoroscopy, comparative oral and nasal air flow measurements, and oral and nasal endoscopy, will aid in assessing the perceived resonance balance. Nasal endoscopy, especially, can be very helpful, as this instrument does not interfere with speech. Larger openings can be visualized through the scope, while the bubbling of mucous may indicate smaller openings that require correction.

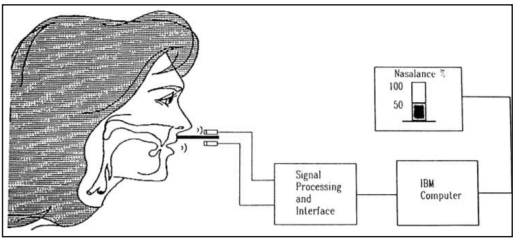

Fig. 19: Schematic view of videofluoroscope

Obturation of Soft Palate Posterior Border Defects:-

Patients in this category have undergone surgical resections of the posterior portion of the soft palate for control of neoplastic disease. They exhibit a variety of defect, but the anterior portion of the soft palate remains intact, with attachment to the posterior border of the palatine bones. It includes the obturation of two prototype defects. First, median posterior border defects, which occur following the surgical resection of lesions of the uvula and the posterior soft palate. Second, lateral posterior borderdefects, which occur following resection of lesions of the anterior tonsillar pillar and the retro molar region. In both instances, the velopharyngeal mechanism may be compromised, and prosthetic obturation is usually the treatment of choice.

Two approaches have been utilized to cross the residual soft palate. One method is to record the soft palate at rest. After the soft palate is circumvented, the obturator is extended superiorly behind the soft palate to the proper level for obturation. This approach will be discussed in this section. A second method is to displace the residual soft palate superiorly with the soft palate extension in order to place the obturator in the proper area in the nasopharynx. Such prosthesis is termed palatal lift prosthesis.

FOR AUTHOR USE ONLY

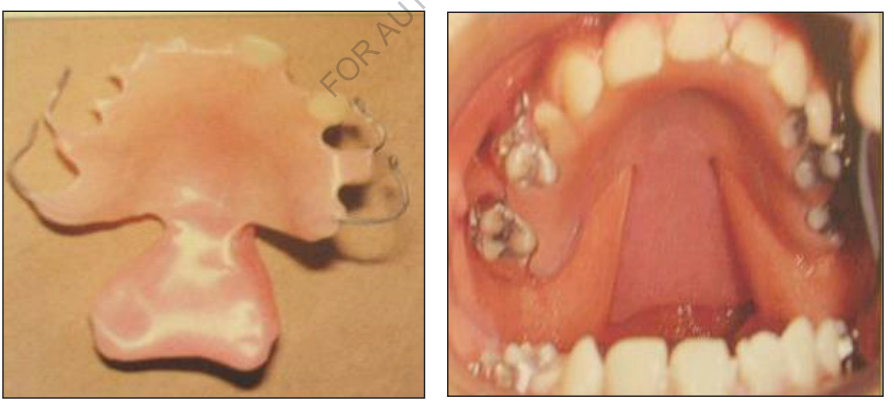

Fig. 20: Obturator with soft palate extension

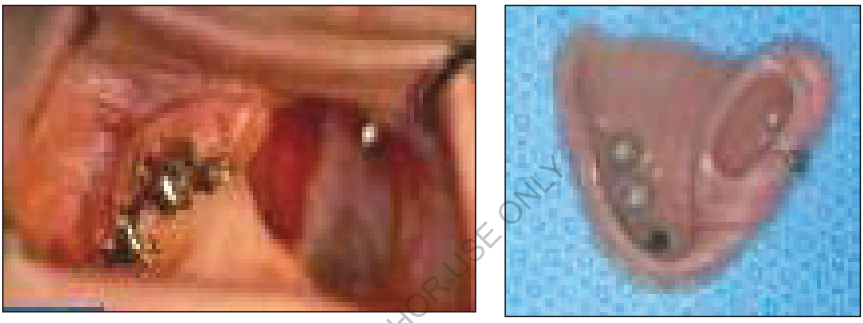
Implant Retained and Supported Obturator Prostheses:-

In patients with soft palate defects, osseointegrated implants enable the design and fabrication of complete overlay dentures with retentive capacities similar to prostheses for dentulous patients with partial denture frameworks. If the soft palate defect has not resulted in the compromise of the posterior palatal seal area, and the residual palatal structures are favorable, two implants, placed into the premaxillary segment in the region of the cuspids, will be a sufficient supplement to the retention, stability and support derived form the residual structures. However, if the defect has compromised the posterior palatal seal area, and /or the residual palatal structures provide insufficient stability and support for the prosthesis, 4 or more implants should be placed.



FOR AUTHOR USE ONLY

Fig. 21: Implant supported obturator

Palatal Lift Prostheses:-

The popularity of the palatal lift prosthesis has increased since it was first advocated by Gibbons and Beumer. This type of prosthesis is especially useful for patients with velopharyngeal incompetence who exhibit compromised motor control of the soft palate and related musculature. Examples myasthenia gravis, cerebrovacular accidents traumatic brain injuries, bulbar poliomyelitis, cerebral palsy, or injury to the soft palate (as sequelae following adenoidectomy, tonsillectomy, or maxillary resections), or with cleft palate patients with palatal insufficiency and submucous cleft palate. The objective of palatal lift prosthesis is to displace the soft palate to the level of normal palatal elevation, enabling closure by pharyngeal wall action. If the length of the soft palate is insufficient to effect closure after maximal displacement, the addition of an obturator may be necessary behind the displaced soft palate. Adequate lateral pharyngeal wall movement is necessary for the lift to be effective. A space for breathing should be present laterally between the displaced soft palate and the pharyngeal walls at rest.

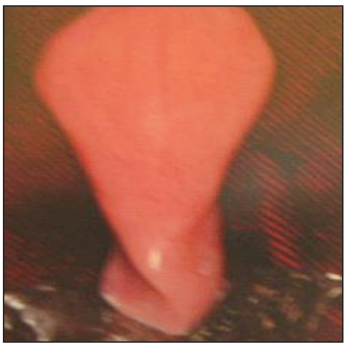


Fig. 22: Palatal lift prosthesis

The advantages of palatal lift prosthesis are as follows:-

1. The gag response is minimized due to the superior position and the sustained pressure of the lift portion of the prosthesis against the soft palate.
2. The physiology of the tongue is not compromised due to the more superior position of the palatal extension.
3. The access to the nasopharynx for the obturator (if necessary) is facilitated,
4. The lift portion may be developed sequentially to aid patient adaptation to the prosthesis.
5. The lift principle has application to a diverse patient population that cannot be treated as effectively with palatal surgery or other types of obturator prostheses.

   A palatal lift prosthesis is contraindicated if: -

   1. Adequate retention is not available for the basic prosthesis,
   2. The palate is not displaceable, or
   3. The patient is uncooperative.

   The displaceability of the soft palate can be checked by the mechanical elevation of the soft palate with a mouth mirror.

FOR AUTHOR USE ONLY

Meatal Obturator Prostheses:-

A meatal obturator prosthesis was first described by Schalit, and later advocated by Sharry. A meatal obturator establishes closure with nasal structures at a level posterior and superior to the posterior terminus of the hard palate. The obturator extends superiorly and slightly posteriorly from the hard palate border, separating the nasopharynx and nasal cavities at the level of the posterior chonchae. There are no

movable tissues in this area and closure is established against the turbinates, the residual vomer (if present), and the roof of the nasal cavity. The palatal defect must be as wide as the area to be obturated, or the rigid meatal obturator cannot be considered. Meatal obturators are used infrequently, but they can be indicated for patients extensive defects of the soft palate who exhibit a very active gag reflex. Indeed, they may be the obturator of choice for edentulous patients when retention is a problem. The meatal extension is not as lengthy as the more conventional obturators previously described, and it may be quite thin in its anterior-posterior dimension, as contact with mobile tissues is not a consideration. Thus, less weight is added to the maxillary complete denture. Also, the downward displacement force from the obturator extension is closer to the supporting tissues of the parent prosthesis.

The disadvantages of this design are obvious. First, the obturator does not enable the patient to control nasal air emission because it is positioned in an area devoid of muscle function. Nasal airflow is created by drilling hole in the obturator or by reducing its lateral extensions. Consequently, the nasal passage is obstructed, leading to hyponasal speech and impaired nasal respiration, or open, predisposing to excessive nasal emission. Therefore, speech therapy is usually not indicated or effective in refining speech after obturator placement. Second, distortions in nasal resonance are evident because the oral cavity and the oropharynx and nasopharynx are increased in size and the nasal cavity is reduced proportionately. Third, the anterior surface of the meatal obturator may act as a dam by hindering normal postnasal drainage patterns, leading to the accumulation of mucous secretions anterior to the prosthesis. Thus frequent removal of the prosthesis is necessary for cleaning. Despite these difficulties, meatal obturator prostheses will improve speech, and they can be adjusted to permit nasal breathing.

FOR AUTHOR USE ONLY

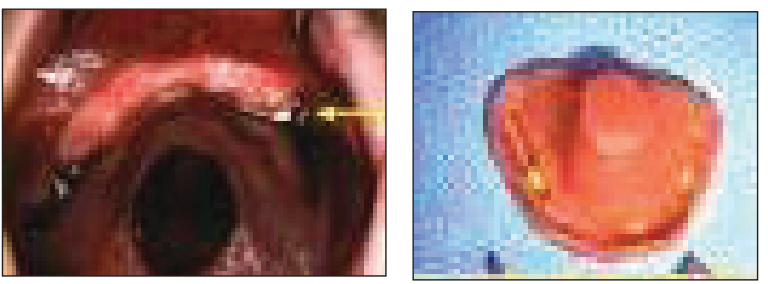

Fig. 23: Meatal obturator

Communication problems associated with cleft palate:-

Clefts of the lip and palate affect speech in two major ways: -
The voice quality becomes deviant, and the articulation is impaired. The voice quality is that of excessive nasality. There are also unique types of articulation errors present in cleft palate speakers. They have more trouble with the plosives, fricatives and affricatives since these require the storing up of air pressure behind the closure or the narrowed opening. Voiced sounds seem to be easier than the unvoiced ones, but the consonant blends present considerable difficulty. The distortion errors are primarily due to nasal emission, the person snorting the sounds out of his nose.

Assessment:-

The assessment of a cleft palate child should be comprehensive and include :-

1. An impression of the child's total communicative effectiveness.
2. Case history information.
3. An oral mechanism inspection.
4. A hearing evaluation.
5. A review of individual's psychological and social adjustment.
6. A language evaluation.
7. An evaluation of the child's velopharangeal competence.
8. Articulation testing.

FOR AUTHOR USE ONLY

Treatment

The goals of therapy are:-

a. To decrease the nasal emission, hyper nasality and the defective articulation.
b. To improve the oral air pressure and oral airflow.
c. To eliminate abnormal foci of tensions and abnormal nostril contractions.
d. To activate the tongue, lip and jaws
e. To improve the respiratory rhythm of speech and their rate and control.
f. To improve velar and pharyngeal contraction.

Air pressure controls:-

Air pressure with in the mouth varies with the various speech sounds. The plosive and the sibilants require the most air pressure. Voiced sounds require less than do the invoiced sounds. Cleft palate patients often use very tight closures and sudden releases. This is unwise since much more air pressure is required for plosives (like /t/ and /d/) than for the loose contact, slow release type.

The fricatives employ a narrow channel for the airflow but cleft palate patients use the narrower ones that require a greater air pressure and so nasal emission tends to occur.

Much of the stimulus valve of a sound can be increased by prolonging its duration. Weaker 's' sound should be held longer. A slightly prolonged /f/ in the word fish even if weaker in airflow will be understood as readily as a quicker, stronger one. Many speech pathologists teach their cleft palate clients to open the mouth widely in speech, as far as they can without appearing abnormal. It improves the speech markedly as any larger opening attracts airflow. Larger mouth openings for the vowels tend to produce looser contacts of the lips and tongue, and they certainly increases the consciousness of the mouth rather than the nose.

Muscle training:-

It is possible to improve the state of air pressure with in the mouth by shutting off the air leak, by improving velopharangeal closure. Many of the muscles are weak and can be strengthened through appropriate. Exercises if surgery or prosthesis has been successful in creating the condition for a possible closure (Mc Willions, Morries, & Shelton, 1984; Karnell and Van Demark, 1986). If the cleft palate patient can flow up a balloon or whistle or if inspection with dental mirror shows good occlusions of the nasopharynx, we should be able to help him use some closure in speech.

FOR AUTHOR USE ONLY

Blowing exercises:-

Blowing exercises have been used more frequently than any other single device for strengthening the palate. Blowing takes air pressure, and if the air is to come out of the mouth, a velopharangeal opening will reduce that pressure enough to reduce the air flow through the mouth to a considerable degree.

Blowing exercises helps the patient to become mouth conscious, they can help him discriminate the two air flow channels; they can help him to increase the amount of oral air pressure needed for good articulations; and they can improve the contraction of the velar and pharyngeal muscles.

PALATOGRAMS

Palatograms are the area of tongue contact for a given sound displayed on an artificial palate through a medium of non scented talcum powder.

Pre-Requisites of Making a Palatogram

1. The artificial palate must be accurately adapted and refined so that it can be worn comfortably without an adhesive until speech is normal and natural. The subject who does not accommodate or who gags after a 15 minutes practice speaking period should not be used, because palatograms of faulty speech would be of dubious value and gagging makes palatography impossible.
2. The subject should be trained to pronounce the sound distinctly, and then to open his mouth with the tongue flat (out of contact with the palate) and not to attempt to swallow until after the palate is removed. Several trials should precede the making of the palatogram to ensure that the patient can pronounce the sound distinctly and immediately open his mouth without a gain contacting the palate with the tongue.
3. The tracing medium should not be distasteful in flavors or appearance and should be of a consistency that will permit ease of application and removes from the artificial palate. The colour of the medium should contrast with the palate sufficiently to display readily the area of tongue contact.
4. The palate must be dried thoroughly before dusting with talc, and care must be taken in inserting and removing the dusted palate to avoid finger contact, which would smudge the tracing. In pronouncing the phoneme, the moist tongue removes the talc from the contact area, leaving a clear tracing.

FOR AUTHOR USE ONLY

A palatographic study of all the vowels revealed tongue palatal contact for all except 'O'. The similarity of the tongue contact area on the palatograms is because phenomes are usually composed of more than one phone and that each phone requires separate articulation. The phone with, occurs singly in pronouncing the vowel 'e' and is prevalent in a, i and u. It occurs as the initial sound in u (ee – o) and as the second sound of a and i (i-ee)

Consonants cannot be used in making palatograms, because the vowels included in the pronunciations involve tongue palatal contact, which would obscure the tracing of the articulation for the stop or affricative. Example: in pronouncing t and d, the occlusive articulations is made first followed by 'e', 'a' follows the

affricative articulations for J and the affricative articulation for K. In pronouncing S, n or l , the mid-vowel 'e' precedes the articulations for the sibilant s, the nasal n, or the lateral l. To make the palatographic study of consonantal articulation, the 'O' was used in conjunction with the consonant to be studied, even though the combination did not result in a standard English work as in pronouncing 'O', the tongue naturally drops back out of contact with the palate and flattens, making it easy for the subject to open his mouth with out raising the tongue.

PALATAL CONTOUR OF THE DENTURE

A few have recognized the importance of palatal contour of the denture for better phonation. **Snow, as early as 1899),** recommended restoring the anterior lingual alveolar area to improve phonetics, particularly the pronunciation of s & sh. **Prendergast (1935**) pointed out that proper thickening of the lingual alveolar area was important for proper speech.

Sears (1949) recommended making a palatogram on cases where the median sulcus of the tongue does not coincide with the midline of the palate. He recommended grooving the palate just above the median sulcus for the patient who had little or no tongue sulcus and thickening this area for the patient who had a deep tongue sulcus. **Pound (1951)** was successful in improving phonetics by contouring the entire lingual aspect of the maxillary denture to simulate the normal palate.

FOR AUTHOR USE ONLY

Speech Tests

The phonetic aspect of denture construction at least deserves equal consideration with esthetics and mechanics and should be checked at the time of the waxed try in when it is possible to alter palatal contour to accommodate speech articulation. The trial denture evaluation should not be considered complete until a phonetic test has been made and enunciation proved satisfactory to both the patient and the operator.

Waxing of the palatal portions of the trial denture should be confined to the area adjacent to the teeth, with just enough wax added to ensure a smooth surface between the base tray and collars of the teeth. It is presumed that the base trays are comfortable, well adapted and approximate the tissues with nearly the same fidelity as anticipated for the completed denture bases. Before the speech tests are started, the mandibular trial denture should be secured with denture adhesive.

1. The first test is of random speech and is best accomplished by engaging the patient in conversation and obtaining a subjective speech analysis by asking the patient how the dentures feel, how his speech sounds to him, and which words seem most difficult to pronounce.
2. The second test is to specific speech sounds. This is best accomplished by having the patient pronounce six or eight words containing the sound and then combining these words into a sentence. The following is a list of the sounds to be tested; opposite the sounds are the words to be pronounced and a sentence composed of these words :-

s and sh	Six, sixty, ships, sailed, Mississippi, sure, sign, sun, shine.	Sixty-six ships sailed the Mississippi. Sure sign of sunshine
t, d, n, and l	Locator, located, tornado, near, Toledo	The locator located the tornado near Toledo.
Ch and j	Joe, Joyce, Joined, George, Charles, church	Joe and Joyce joined George and Charles at the church.
K	Committee, convened, political, convention, Connecticut	The committee convened at the political convention in Connecticut.
f and v	Vivacious, Vivian, lived, five, fifty-five, fifth, avenue	Vivacious Vivian lived at five fifty-five Fifth Avenue.

FOR AUTHOR USE ONLY

In the third test, the patient is asked to read a short paragraph containing an abundance of s, sh, and ch sounds.

If the patient can complete the speech test distinctly, with no difficulty, and if his random speech satisfies him and the operator, it would be unwise to contour the palate to solve a speech problem that does not exist. If, however, problems are encountered in one or more of the areas tested, then palatal contour is indicated and can effectively be accomplished by palatography.

If the palate is to be altered, the entire palate should be contoured to accommodate tongue contact for all palatal consonants. This is best accomplished by systematically displaying each contact area with a palatogram and establishing normal tongue contact.

Palatography for Proper Palatal Contour

The only additional equipment necessary for palatography is some non-scented talc, in inexpensive soft bristle brush for dusting the talc on the palate, and a glass marking pencil to outline the contact area. Palatograms can be easily and quickly made on the trial denture if the following steps are recalled:-

1. Use o with the consonant to be studied, even though the combination is not a word; i.e., to study k, use ko; to study ch; use cho.
2. Train the patient to pronounce the sound and open the mouth without again contacting the palate.
3. Dry the palate thoroughly before dusting on non-scented talc (do not use regular or surgical talc) and shake off the excess powder.
4. Avoid touching dusted palate with the fingers during insertion, but ensure that the denture is well seated before the sound is pronounced.
5. Be sure the patient makes definite palatal contact in pronouncing the sound, but avoids palatal contact after opening the mouth.
6. Avoid contacting the palate with the fingers when removing the denture.
7. Outline the contact area with a wax carver where wax is present, and with a glass-marking pencil where the base tray is exposed.

FOR AUTHOR USE ONLY

To avoid overlapping the tracing and recontouring one contact area to accommodate another, a sequence of palatograms should be followed, and waxing of the palate should be accomplished in steps. First, and s and sh palatograms are made and outlines on the base trays. Where wax is present, the palatogram is outlined with the carving end of the wax spatula; where the base tray is exposed, the outline is made with a glass marking pencil. Before waxing is commenced, the patterns for s and sh should be reviewed. The tongue contact for s is always higher and more anterior on the palate, so that the outline for the s palatogram is the high line and includes some of the anterior teeth, and the sh line is always lower and includes fewer anterior teeth. The sh line (low line) is used as a guide in waxing the posterior alveolar area, and the s line (high line) is used as guide in waxing the anterior alveolar area. The anterior portion of the sh tracing is not waxed until last. Waxing is started around the first molar by adding enough wax to provide a 1-mm margin at the collar. Next, the low tracing line on the palate is sighted directly below this tooth, and enough wax is added to the palate to permit an even contour between this line and the margin of the molar. Then wax is added around the anterior teeth delineated by the s tracing to provide a ½ mm margin at the collars. Enough wax is then added

between the tracing line and teeth to present an even contour. Waxing in the bicuspid area is accomplished by using the anterior and molar regions as a guide for adding wax around these teeth to complete for smooth, even contour between these waxed areas and the palatal tracing line. Waxing around the second molar consists of adding enough wax around this tooth to complete the contour between palatal tracing line and the waxed first molar area. After waxing on the other side of the palate is completed, a palatogram should be taken to cheek to contour. If the area is properly contoured, the tongue tracing line should be even and about 2mm above the original. If the tracing line rises abruptly in a specific area, that area is too thick and should be reduced until the tracing line is even. If the tracing line drops abruptly in a specific area, that area is not thick enough and additional wax will be needed to provide an even tracing. If the entire tracing rises markedly, the area has been over contoured and should be reduced.

The photographs of the waxing procedure are of a case with considerable alveolar ridge resorption, and using the palatogram to outline the area and waxing in steps as described should aid the beginner in establishing normal tongue contact for these cases. After some experience, the entire outlined areas can be waxed in one step.

FOR AUTHOR USE ONLY

The palatogram can be used effectively for any case, including the immediate denture, if the pattern for normal tongue contact is kept in mind and if sensible observation is employed.

The line on the palate outlining the palatogram represents the lowest point of tongue contact in pronouncing s, and the area between this line and the artificial tooth should be of even contour and gradual slope without excessive convexity or concavity. The amount of wax needed to complete this contour is dependent upon the extent and degree of alveolar resorption, and wax should be added only where necessary to compensate for alveolar deficiency. Many times it is not necessary to add wax as far down as the tracing line to complete the contour, and sometimes, as in the case of slight resorption or the immediate denture, it is not necessary to add wax at all, because enough of the alveolar ridge remains to provide proper contour to the base tray.

After lateral tongue contact for s has been established on the trial denture, the speech tests should be repeated, and if speech is satisfactory, further contouring is

unnecessary. However, it is usually necessary to contour the anterior aspect of the palate to facilitate proper s pronunciation.

By using the palatogram to establish normal tongue blade contact in pronouncing s, appropriate portions of the lateral aspects of the anterior alveolar area are included in the contour, leaving only the region between the lateral contact areas to be considered. The area of this region, which is the most critical to proper s pronunciation, is the area midway between the lateral contacts and directly above the median sulcus of the tongue. In pronouncing s, the tongue contacts the alveolar area to occlude the lateral portion of the oral cavity and form a channel for the air stream between the median sulcus and the palate. This channel narrows to a groove at the tongue apex to constrict the air stream, so that is escapes as a hiss. Normally, this jet of air exits at the incisal edges of the teeth to be heard as the typical s, but on the denture, where tooth arrangement has been altered to accommodate mechanics and esthetics, it is usually necessary to provide a path of exit on the palate in the area directly above the groove in the tongue apex. This is best accomplished by inserting the trial denture and instructing the patient to pronounce ess (not so) and hold it so that the groove in the tongue apex can be observed. The chair should be tilted back and slightly raised so that the opertor can look up and into the oral cavity to determine the character of the groove and its proximity to the palate. It is the area directly above the groove that must be altered according to the fault in pronunciation. If the patient whistles and hisses when pronouncing s, the area between the groove and denture base is excessive and will need to be thickened. For the patient with a deep groove (this is common), a slight elevation is usually required. If the patient lisps (substitutes th for s or has a muffled, indistinct s, there is not enough space between the groove and the denture base, and the area will need to be thinned. If the groove in the tongue is broad and shallow, a depression in the denture base may be required, and if there is no groove in the tongue, a groove on the denture base directly above the median sulcus, as recommended by Sears, will be necessary. If the patient substitutes sh for s, the jet of air is probably escaping toward the vault and the area above the groove will need to be extended toward the tongue. This extension must be made with care, because overextension will occlude the air stream and etts will occlude the air stream and sh will be substituted for s.

FOR AUTHOR USE ONLY

There is no simple way of correcting faulty s pronunciation. The fault must be analyzed the area contoured, and the sound tested, then reanalyzed, re-contoured, and retested until satisfactory pronunciation is attained. The words best suited for testing are short words containing the ess sound, such as “hess,” “guess,” “less,” “mess”.

The time required to correct an error in s pronunciation is time well spent, because it is the commonest and most persistent oral inaccuracy of the denture patient and the one that may remain as a characteristic denture whistle to belie the denture.

Proper palatal contour is the key to proper s pronunciation, or all other pronunciation for that matter, and that the palate can be contoured to accommodate phonetics for any sensible both arrangement, including the bizarre class II and severe class III jaw relation cases. There is little doubt that the character of the air stream directed between the upper and lower incisors in pronouncing s will be affected by the relationship of these teeth at the time of exit; therefore, it is possible to soften or sharpen the s by increasing or decreasing the amount of over jet. However, the direction of exit can be controlled by palatal contour to permit considerable leeway in anterior tooth arrangement and still provide good quality to this sound.

Contour of the anterior palate is completed by adding the minimum amount of wax between the low tracing line for sh and the lateral and mid-palatal contoured areas to make a smooth junction. Care should be taken not to thicken the lateral contact areas or alter the median contour. To ensure that enough wax was added to provide tongue contact for the occlusives t, d, and n, a palatogram of t, to should be made. After completing the anterior palatal contour, usually no further contouring is necessary, but the speech tests should be repeated with particular attention given to the pronunciation of ch and j, because occasionally, in contouring the mid anterior alveolar region, wax builds up on the palate below and will interfere with the pronunciation of these sounds. If this happens, a palatogram should be made for ch, cho to outline the area of tongue contact so that alteration can be confined to that area.

FOR AUTHOR USE ONLY

The use of palatograms for contouring the entire alveolar area will be useful to those who adhere to the philosophy of placing the artificial teeth in the same relative position as the dentition. If the posterior teeth are arranged near the center of the alveolar ridge and the anterior teeth arranged to occupy approximately the same position as the originals, then a palatogram on the trial denture is an aid in contouring the palate for normal contact. If, however, the philosophy of arranging teeth according to mechanical advantage is adhered to, then the palatogram would be of limited value in contouring the posterior alveolar area, because the posterior teeth will occupy a position lingual to the center of the ridge on this denture. A palatogram of the s on the trial denture in this case would reveal limited tongue contact in the molar alveolar area, progressively increasing to normal contact in the anterior region,

and adding wax to simulate a natural alveolar contour in the molar area would be a grosser insult to phonetics then not adding wax to complete alveolar contour in this area on the denture with center of the ridge tooth arrangement. Phonetics is better served in these cases by keeping the posterior alveolar area as thin as possible and confining palatal contour to the anterior region. Thickening the vault to narrow the channel for the air stream, facilities s pronunciation in this type of denture, but before wax is added to the vault, a palatogram of k, ko should be made to delineate the area of posterior palatal tongue contact so that this area can be excluded from the waxing.

Satisfactory phonetics can be accomplished with a constricted posterior tooth arrangement so long as the anterior teeth are arranged to permit normal palatal contact. However, if the anterior teeth are arranged lingual to the natural tooth position, they will interfere with the tongue in making palatal contact and impede or occlude the air stream after contact has been made in pronouncing s. For this reason, in cases with severe resorption, where the anterior ridge affords no clue to natural tooth position, a palatogram can advantageously be used in arranging the teeth to ensure that tongue palatal contact is not jeopardized. Considerably more leeway is permitted in arranging teeth toward the labial, because tongue contact is unhampered and the palate can be contoured to accommodate the arrangement.

FOR AUTHOR USE ONLY

CONCLUSION

Speech difficulties as sequelae of oral rehabilitation with complete dentures are generally a transient problem. When encountered the difficulties may not be easily solved. Therefore efforts should be made to avoid them by pretreatment records or assessment of speech and provision of information to patients about likely initial deviation from normal speech, immediately following oral rehabilitation. If persistent difficulties to pronounce certain sounds or other speech disorders persist for more than 2 to 4 weeks, the following protocol is recommended –

1. If the patient has the previous complete denture experience, compare the new set with the old one to diagnose possible design differences of significance for speech production.
2. Make the necessary modifications; soft wax might be helpful.
3. Have the patient's hearing checked. An auditory deficit will prolong the adaptation period and render it more difficult.
4. If the reported/ perceived problem cannot be resolved by dental methods, the patient should be referred to speech pathologist.

FOR AUTHOR USE ONLY

In the past speech therapist have been expected to undertake the diagnosis as well as the management of ones who suffer from speech disorders. Yet a high proportion of children or people referred to speech therapist suffer from diseases which directly affect the structure and function of lips, tongue and palate, or they suffer from conditions which are the primary causes of their speech difficulties, e.g. Mental defect or hearing loss, many show psychiatric abnormalities which may be primary or secondary to their speech defect.

Therefore it is important that the assessment of the person should be regarded as one that merits a team approach, though the team may differ in content according to the nature of the child disability – with the speech therapist as the constant member of the team.

In maxillofacial prosthetics, the clinician may have responsibility of reestablishing velopharyngeal integrity to provide the potential for acceptable speech.

The largest group of patients with defective speech is the patients with congenital clefts of the soft palate. Most acquired soft palatal defects result from

surgical resection of neoplastic disease/ trauma. Prosthodontist play an important role in restoring speech in these patients by giving palatal; lift prostheses.

Not only the face but speech also reflects an individual's inner being. Any abnormality or defect in the same can affect his/ her psychology and social behavior. Hence a prosthodontist play a pivotal role in understanding the basic mechanisms involved in the various speech pathology and provide prudent treatment for the same to enhance an individuals personality.

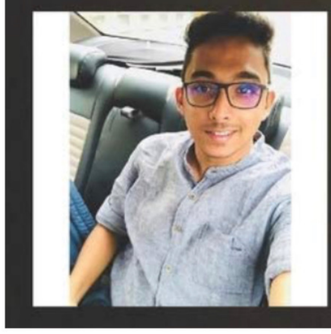
ADVANCED DIAGNOSTIC AIDS IN IMPLANT DENTISTRY

Dr. Faisal Sultan

The ideal goal of diagnostic procedures is the earliest possible identification of the disease process. Conventional efforts evaluating inflammation and past evidence of tissue breakdown remain the standard for disease evaluation. However, evaluation cannot reliably identify sites with ongoing periodontal destruction and does not provide any information of the cause of the condition and the patient's susceptibility to the disease, whether the disease is progressing, or is in remission or whether the response to the therapy will be positive or negative. This is an aid to clinical decision-making, done on patients who are symptomatic and is usually more expensive and can carry more risks than screening tests. Diagnostic tests are also done after a positive screening test to establish a definitive diagnosis and are often called confirmatory tests.



Dr. Faisal Sultan is a practicing periodontist and implantologist in India. Completed his undergraduate in the year 2016 from kerala. and masters in periodontics from Mumbai. He is practising since 2016 and has a well established practice in Kerala, south of India.

When Fixed Meets Removable: Custom porcelain crown to enhance esthetics in cast partial denture

Dr. Sumit Bedia

Bharati Vidyapeeth Dental College & Hospital, Navi Mumbai

Introduction: With an increase in demand for esthetics, emphasis must be given to proper selection of teeth being replaced while fabricating any dental prosthesis and removable partial dentures are no exception. While fabricating cast partial dentures, resin teeth are routinely used because of their inherent advantages. However, resin teeth when used to replace anterior single tooth edentulous space may frequently pose problem in shade matching with adjacent natural or restored artificial teeth. This necessitates characterization, the results of which may not be predictable and long-lasting. Use of porcelain denture teeth too do not seem to be a viable option in such cases as these are available in specific shades, are difficult to grind and adjust, are costly and their retention to denture base is always a problem. Further, most of the alloys routinely used for cast partial denture framework fabrication such as cobalt-chromium alloys, exhibit poor bond characteristics with porcelain unless a metal conditioner is applied which increases overall cost.

Methodology: This clinical report describes an innovative technique of using a fixed custom porcelain-fused-to-metal crown (PFM) as a part of removable cast partial denture to match with shade and appearance of adjacent multiple PFM restorations.

Result: NA

Conclusion: This simple and predictable technique can help overcome the problem of shade mismatch which may exist between stock resin tooth of partial denture and adjacent porcelain restorations and it does not require any special armamentarium.

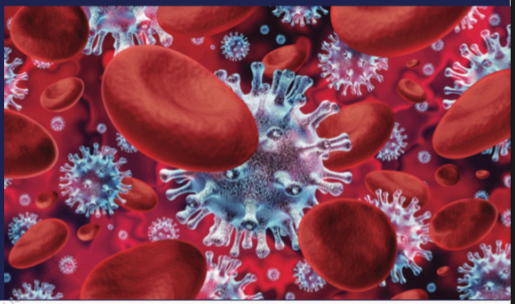
The biological concepts of wound healing, the type and stages of wound healing along with the process of healing and its complications related to the oral periodontium is well explained in this book. Concept of wound healing is well explained at both histological and clinical levels. It also includes healing following various periodontal procedures and recent advancements to accelerate the rate of healing process in periodontology.



ERROR AUTHOR U

Dr. Aishwarya Udawant is a M.D.S. in Periodontology & Oral Implantology. She did her graduation from Dr. D.Y. Patil Dental College & Hospital and post graduation from Bharati Vidyapeeth Dental College & Hospital. She has a bright academic carrier throughout. She has also participated and presented many research papers in national conferences.

Wound Healing In Periodontology

Biological Concepts & Recent Advances

LAP LAMBERT Academic Publishing

Gingival crevicular fluid (GCF) is defined as the tissue fluid that seeps through the
crevicular and junctional epithelium. Many studies on gingival crevicular fluid extend over a period of about 50 years, however its presence is known since 19th century. With so much research now available, it is obvious that GCF provides a unique window for analysis of periodontal condition. The book aims to discuss the clinical significance of GCF, its constituents & methods of collection & processing. The author hopes to guide the readers to understand the role of GCF influencing periodontal health status.

Dr. Divyangana Vashi is a postgraduate dental student, specializing in the field of Periodontology and implant Dentistry. Her keen interest in the field of clinical research led her to pursue the following topic as her library dissertation for fulfillment of her degree of Master of Dental Surgery.

Knowledge of the biology of the pulp and dentin, coupled with an understanding of the materials and techniques applied to tissues, will provide a sound basis for restorative dentistry. Such knowledge will make it possible for the dentist to select materials and methods that will produce no or favorable reactions in the tissues to optimally conserve damaged teeth. It should also provide opportunities for new biologic approaches to restorative dentistry. Thus, any commonly used procedures in restorative dentistry endanger health of pulpal & peri radicular tissues more than the disease processes they are intended to correct. These procedures will contribute to reversible & irreversible changes or alterations in the dental structures. The diversity & complexity of these tissues compel us to think how to avoid this and what effect it will have on the pulp & the peri radicular tissues. To optimally achieve this goal, clinicians working with dentin and pulp must have detailed knowledge of normal tooth structure; age-related changes; tissue responses to caries, trauma, and restorative procedures; and the effect of the application of different agents and materials on the tissues.

I have completed my BDS from YCMM & RDF's Dental College and Hospital, Ahmednagar in 2013 and did my internship programme in Government Dental College and Hospital, Mumbai in 2014. Currently Iam pursuing my masters in Conservative Dentistry and Endodontics from Bharati Vidyapeeth Dental college and Hospital, Navi Mumbai.

The aim of developing computer controlled production technologies for use in restorative dentistry is to improve the quality of the construction units and at the same time to lower manufacturing costs by simplifying the method and reducing the production time. Many different computer systems have already been discussed in the literature for dental applications and have also to some extent been used clinically. The computer assisted systems known today differ mainly with regard to the type of three-dimensional data recording system used to image the prepared tooth. In contrast, the automatic manufacturing (CAM) of the pieces is quite similar and consists mainly of a numerically controlled (NC) machine with a material specific milling unit that can be moved in multiple axes in relationship to the piece being worked on.The use of computer technology is justifiable only if computer assisted design (CAD) and computer assisted manufacturing (CAM) produce dental reconstructions that fulfill or improve existing material characteristics and/or clinical quality.

I have completed my BDS from CDCRI,Chhattisgarh in 2009 and currently pursuing my masters in Conservative Dentistry & Endodontics from Bharati Vidya Peeth Dental College &Hospital, Navi Mumbai.

The trend toward a heightened awareness of esthetics has challenged dentistry to look at dental esthetics in a more organized and systematic manner, so that the health of patients and their teeth is still the most important underlying objective. But some existing dentitions simply cannot be restored to a more pleasing appearance without the assistance of several different dental disciplines. Today, every dental practitioner must have a thorough understanding of the roles of these various disciplines in producing an esthetic makeover, with the most conservative and biologically sound interdisciplinary treatment plan possible.
This book will brief about approaches towards achieving good and healthy smile.

An enthusiastic periodontist and implatologist, searching the solutions for better oral health and learning the new paradigm of dentistry.

With the evolution and advancements in dental science, various new techniques and methods for the replacement of missing teeth have come into foray. Replacement of missing teeth with dental implants have now become the most sought-after treatment modality. Implant overdentures are increasingly used as a viable option to restore edentulous patients and mandibular overdenture has been advocated as a minimum standard of care for such patients, especially in developed nations. Compared with conventional removable dentures, the implant overdenture prostheses offers increased longevity, improved function, bone preservation, and better psychologic results. This book provides an overview on the various techniques and attachments that are available for implant supported overdentures.

Dr Shruti Sai is currently pursuing her Master in Dental Surgery in Prosthodontics at Bharati Vidyapeeth Deemed to be University Dental College and Hospital, Navi Mumbai, India. She has presented many scientific papers in various conferences. Her keen interests are implant and fixed prosthodontics and has an indination towards academics.

The concepts of biomedical engineering principles which are applied to the living systems has unfolded a new era in the diagnosis, treatment planning & rehabilitation of patients. One such aspect of this field is the "Biomechanics" which concerns with the response of biological tissues to the applied loads. It uses the tools and methods of applied engineering mechanics to search for a structure-function relationship in the living system. Advancements in prosthetic implant and instrumentation design have been evolved due to the mechanical design optimization theory and practice. This book attempts to provide with the fundamental concepts and principles of dental biomechanics as they relate to long-term success of dental implants and their restorative procedures.

Dr. Akshaya Ambokar is a third year postgraduate student at Bharati Vidyapeeth Dental College and Hospital, Navi Mumbai in the department of Prosthodontics. She has completed her BDS from prestigious Nair Hospital Dental College, Mumbai.

Endodontic Radiology n a distinctive reference that covers all aspects of radiographic imaging in relation to endodontics.

The vistas of endodontic diagnosis are ever evolving. Thus this book comprises of various traditional radiographic techniques and also includes information available on latest equipment like digital radiograph, Computed Tomography, Tuned aperture CT, Cone Beam Computed Tomography, MicroCT, Ultrasonography and Magnetic Resonance Imaging.

Chapters in this book explain importance of radiography in endodontics, general radiographic techniques, intraoral techniques, extra oral techniques with its principles, advantages and disadvantages, hazards of X ray radiation and radiation protection.

It will aid to select appropriate diagnostic tool. Selection of best possible diagnostic tools for clinician's toolkit will help him or her patient along a safer and surer path of endodontic treatment.

Along with overview of equipment, this book also includes radiographic interpretation which will help to rule out diagnosis of various diseases.

Oral squamous cell carcinoma is one of the leading cancers of the oral cavity that involves a complex pathogenesis. Epithelial Mesenchymal Transition (EMT) is suggested to play a significant role during cancer progression and metastasis. EMT markers are used in oral cancer to identify tumor invasion and metastasis. This book emphasizes the various mechanisms of EMT along with various molecules involved in EMT and aims to facilitate the readers to acquire a sound knowledge on the process of EMT.

The book of Forensic odontology has been written to simplify the understanding of the forensic science which is a vital instrument for the detection or investigation of crime and the administration of justice, providing crucial information about the evidence found at crime scene, it is especially important that the training and education of forensic scientists provide a solid scientific background and a broad base in criminalistics. An attempt has been made to explain the concept of forensic odontology in simple language and simplest possible terms. . Awareness and applicability of Forensic Odontology in the Indian Defence Forces would be of great help for better and accurate record keeping of the dedicated and vigilant warriors of our army. These records will be of great help for easy recognition of our army men at the time of calamities, wars, and other difficulties. It would also be useful in the identification of terrorists who our country and travel easily in disguise.

Genetics in Orthodontics

An Overview

LAP LAMBERT Academic Publishing

The book of Genetics in Orthodontics has been written to simplify the understanding of the Role of Genetics in Orthodontics. Tools from genetics and applied translational research will permit precision Orthodontics. During the past 20 years, significant advancements in understanding the genomic basis of craniofacial development and the gene variants associated with dentofacial deformities have resulted in a convergence of the principles and concepts in genetics and in Orthodontics that will lead to significant advancement of Orthodontic treatments. A modern genomic basis will establish major improvements in the treatment of malocclusion and dentofacial deformities as well as many other areas of concern to Orthodontists through the assessment of gene variants on a patient-by-patient basis. This book will help the readers to understand the new concepts of Genetics which have been introduced in the field of Orthodontics.

Dr. Shraddha Shetti-Golgire has completed master in Orthodontics and Dentofacial Orthopedics as well as laser therapist She has interest in genetic basis of Orthodontics.

Connective tissue permits almost every part of the body, providing intimate support for blood vessels and nerves of all sizes. It is also the usual arena for the process of inflammation, which commonly occurs when some part of body is invaded by pathogenic micro-organisms. One of the most obvious roles is to hold together and nourish the other tissues of the body. It is able to carry out these functions because it produces relatively abundant amounts of intercellular substances.

Dr. Dilip B. Magdum is Professor and Head, Department of Oral and Maxillofacial Patholgy at Bharati Vidyapeeth Dental College and Hospital, Sangli. He completed his MDS(Oral and Maxillofacial Pathology)in 2004 from Nair Hospital Dental College, Mumbai. He was also EC member of faculty of Dentistry in BharatiVidyapeeth deemed to be university,Pune

ARTICLE "Comprehending Viral Diseases with Sushruta's Insight"

By Dr. Mrs. Madhuri P. Bhide

Covid 19 Pandemic has collapsed all the economic stability as well as wobbled the medical field. How the tiny and microscopic virus has done as much disaster and harassed the world? When the whole world is questioned and unanswered What our time tested and righteous Ayurved opines about it?

Sushrut the master Surgeon has quoted about the tiny organisms which may harm the mankind in his special chapter "Amanush Upasarga Pratishedh Adhyay" (Ref. Sushrut Samhita Uttartantra 60/3). 'Amaush Upasarga' means the diseases caused due to the organisms or other factors such as undue and erroneous force of planets. In such Agantuk disease (external factors) there is no acute role of any human being of consuming 'Apathya Ahar-Vihar'. The commentrator of Sushruta ,Dalhan explains microorganisms as 'Amanushani- Bhutani'.

These are termed as "Rakshasaha ,Nishacharaha, Makshikaha" which destruct the tissues and cause disaster in the body. Specially Sushrut has warned a doctor to avoid the contact of these infections from the wounds as wounds are open and organisms get easy entry in body.

निशाचरेभ्यो रक्ष्यस्तु नित्यमेव क्षतातुरः | Su U. 60/3

Sushrut has explained how they enter in body and person gets infected.

यथा देहं च देहधृक् ।

विशन्ति च न दृश्यन्ते ग्रहास्तद्वच्छरीरिणम् ।।१९।।

Su U 60/19

The way how suksma and invisible soul enters in body, these micro-organisms enter silently and we do not know when we get infected.

As we know virus are innumerate, Sushrut says they are crores and crores so there is no need to name them. Swine flu virus, corona virus, saars, british virus and so on …….many many more to arrive worldwide even with their mutations.

तेषां ग्रहाणां परिचारका ये कोटीसहस्रायुतपद्मसङ्ख्याः ।

असृग्वसामांसभुजः सुभीमा निशाविहाराश्च तमाविशन्ति ।।२२।।

Su U 60/22

All these viruses are called as "Bhima" and "Atyarth Bhayankar" means the dreadful. The bhutas provoka tridoshas and act as poison and suddenly create diseases.

वैद्यातुरौ निहन्युस्ते ध्रुवं क्रुद्धा महौजसः ।।५५।।

Su U 60/ 54

These can create a dreadful situation and hence doctor should be competent and well equipped.

How to prevent their entry in the body and how to repel them ?

Now a days we use sanitizers and disinfectants ,Sushrut has advised some effective measures for it.

सर्षपारिष्टपत्राभ्यां सर्पिषा लवणेन च ।

द्विरह्नः कारयेद्धूपं दशरात्रमतन्द्रितः Su Su 19/28

Burn the Mustard seeds, Neem leaves, Saindhav salt and cow ghee and make Dhupan twice a day without any fail for 10 days. The dhupan is called as 'Rakshoghna vidhi' and repels the Small organisms. Due to fumigation the rakshas or bhuta become Hatoujas it means they become inactive or their liveliness becomes less. Thus, this bhutas not only merely get repelled but also become Inactive to increase doshas in the wounded patient.

All the world is facing disaster of severe viral infections but as we have come across to the fact that its response to everyone is different.

Many of the patients who had suffered from common cold and fever due to the seasonal changes but all had not faced respiratory arrest. A very few of them that is only ten percent have been faced morbid situation. It is the basic query that why`` immunoresponce of each person is different?

1) According to Sushruta, the 'Atmavan' person who undergoes ideal diet, has equilibrium of doshas and whose dhatus are in healthy condition may suffer from common cold or fever due to the doshavriddhi but can repel the viral infection without any major fatal problem like respiratory distress.

सर्व एव व्रणाः क्षिप्रं संरोहन्त्यात्मवतां सुभिषग्भिश्चोपक्रान्ताः;

अनात्मवतामज्ञैश्चोपक्रान्ताः प्रदुष्यन्ति, प्रवृद्धत्वाद्दोषाणाम् ।।

Sushrut has wisely advised that those people who are "Atmavan "will get the wounds fast cured without any suppuration or complications due to healthy tissues but those with "Pravriddha doshas" take a long time to heal though treated by a great physician and with potent medicines. Though he exemplifies about the wound this phenomenon is applicable to other diseases also.

Atidoshakar ahar leads to suppuration of the wound.

Sushruta refers to the Hitakar Ahar quoted by him.

हिताहितीये यच्चोक्तं नित्यमेव समाचरेत् ।

CONFERENCE PROCEEDINGS

Virtual International Conference On Recent Advances & Challenges in Sports Rehabilitation

5th June to 7th June 2021

Background: Smartphones are a very popular and useful devices. There is an ever-increasing use of smartphone in the young population allowing everyone to access the internet, social communication & to entertain themselves anytime anywhere. But over smart phone use can also be related to some somatic complaints, anxiety, depression, stress, insomnia and increasing loneliness. Thus, the current study aims to study the relation between smart phone addiction and anxiety.

Methodology: 30 young adults (18-25 yrs age, 14 females and 16 males) agreed to participate in the study. Demographic details, smartphones addiction scale – short version (SAS-SV) and Hamilton's anxiety scale (HAM-A) were filled via an online questionnaire, to assess the level of smartphone addiction and severity of anxiety.

Result: This study showed that the young adults with mean age 21.55(1.29), have a mean 16.89(9.07) on HAM-A and a mean of 31.7(11.21) on SAS-SV. The correlation between SAS-SV and HAM-A is 0.324. The study showed that 73.4% are high user of smartphones (total score of 25 or above) and 16% of our subjects fall into the category of "moderate level of anxiety" individuals (having total score 18-24) 24% fall into the category of "highly severe level of anxiety" (total score of 24 or above).

Conclusion: The current study shows that smartphone overuse is moderately responsible for increasing anxiety among the participants. As young adults need to develop their skills & knowledge to be competent professionals, they should use smartphones appropriately and be cautious about the negative effects of phone addiction on anxiety.

Holistic Outlook of Traditional Medicine in Sports

Pooja Raj[1], Ravindra Patwardhan[1], Kirti Bhati[1]

[1]Department of Swasthavritta and Yoga, Bharati Vidyapeeth (Deemed to be University) College of Ayurved, Pune, Maharashtra, India

Background: In ancient vedic era, sports was adressed as "krida" (playing, skipping) and "vyayama" (toughening up, physical exercise) for "exercise" and this demonstrates the ayurvedic principle of balance as too much activity creates imbalance as much as too little.Vyayama (exercise) helps to get rid of heaviness and stiffness of the body as it burns Ama (digestion impurities) and creates more flexibility, lightness, smoothness and easiness which are three pillers of fittness.Sports medicine has two goals to achieve, primarily physical and mental fitness and second goal is treating the sporting injuries of the sportsman. Ayurved can help to achieve both of them through Panchakarma, yoga, Rasayana, Marma Chikitsa etc and herbs which add extra healing edge to the body injuries. Discipline is a bridge between goals & accomplishment which is very important for any sports person and these rules are explained well in Dincharya, Rtucharya and Ratricharya.

Purpose: The present paper intends, in the above context, to identify the possible contribution of Ayurved in the field of sports medicine.The aim of this review is to bring the ayurvedic outlook with various treatment modalities into limelight & factuall research evidence validating it.

Methodology: Traditional Medicine recommendations for prevention & curation of injuries in sports were rationally reviewed in light of published information from several scientific articles & literature

review from Vedic texts were taken into systemic review study.

Conclusion: Ayurvedic therapy with new modern technology in sports if used together,can enhance performance, physical fitness and assist in various sport injuries with several concepts in Ayurveda & rules & regimens for healthy living as a goal for a sports person.

Importance of Yoga in our Daily Life

Sajad Ahmad Dar[1], Vivek Gulhane[2]

[1]Sant Gadge Baba Amravati University, Amravati, Maharashtra, India
2P.G. Jain Arts College Ansing, Washim, Maharashtra, India

It is rightly said that if we want to maintain a balance between oneself and environment then yoga is necessary for every human. We can't deny the fact that since ancient times in India yoga is being practiced. The 'yoga' word is derived from the Sanskrit which means 'to join or to unite'. Exercises of yoga have a physical effect and also bring a balance between body, soul and mind. Several years ago, sages analysed nature and cosmos through meditation. It is rightly said that if we want to maintain a balance between oneself and environment then yoga is necessary for every human. We can't deny the fact that since ancient times in India yoga is being practiced. The 'yoga' word is derived from the Sanskrit which means 'to join or to unite'. Exercises of yoga have a physical effect and also bring a balance between body, soul and mind. Several years ago, sages analysed nature and cosmos through meditation. Yoga can be practiced in any age it is suitable for people of all ages and requires no 'stunt' skills. It should be included in our daily life. Path of self-knowledge and self-realisation can be attained via positive thinking, perseverance, discipline, right orientation, prayer as well as humble and kindness. The importance of life is the health of our body. If health is not good then we will not be able to achieve our goals or will not remain happy. It is rightly said that "Health is not everything, but without health everything is nothing.

Effect of Moderate Intensity Resistance Training with Blood flow restriction On Muscle Strength and Girth in Young Adults – A Randomized Control Trial

Tanya Gujral

Noida International University, Greater Noida, Uttar Pradesh, India

Objective: To examine the effects of moderate intensity resistance training with blood flow restriction on muscle strength & forearm girth.

Method: Total of 39 students enrolled in this study were divided into three groups that is group A (control group), group B and group C. Group A performed exercise training without restrictive pressure, group B & C performed exercise training with 50mmHg and 75mmHg respectively. Both the outcome measures were evaluated on day1 and day 12th with the help of digital dynamometer and measuring tape.

Results: Repeated measure ANOVA with Post hoc analysis was done using SPSS software version 20. The result of the study showed significant ($p \leq 0.05$) within subject improvement in muscle strength and muscle girth in all the three groups. However, there was significant improvement in muscle strength was found in between group analysis ($p \leq 0.05$).

Conclusion: The results of the study can be concluded as the partial blood flow restriction (50mmHg)

To Assess and Correlate Heart Rate Variability, Resting Heart Rate and Body Composition in Judo and Wushu Players

Sapna Yadav[1], Gaurav Kadyan[1]

[1]Department of Physiotherapy, Indian Spinal Injury Center, New Delhi, India

Background: Adequate In any combat sport, where competitors are divided by weight classes, optimal body composition is a major concern. Thus, athletes attempt to maximize the amount of lean tissue, minimize the amount of body fat, and minimize total bodyweight. Monitoring the status of the autonomic nervous system (ANS) via the measures of heart rate (HR), including the variability of HR and HR at rest can be used to understand the physiological state of body.

Purpose: This study aims to assess and Correlate Heart rate Variability, Resting Heart rate and Body composition and HRV in judo and wushu players.

Materials and Methods: Subjects were divided into 2 groups i.e., Judo and Wushu group containing 20 players each. Age (19.85±1.805), height (171.37±5.98), Weight (72.87±11.8), BMI (24.77±3.56). Anthropometric profiling was done with the help of Harpenden calliper and measuring tape to measure the skinfold thickness and body circumference respectively. HRV recordings were taken with the help of Heartwear shimmer ECG device in sitting position in a quiet environment.

Result: Subjects showed significant negative correlation of Resting heart rate with HF, BMI showed significant positive correlation with LF/HF, whereas Body fat % showed significant positive correlation with LF/HF.

Conclusion: There is significant negative correlation between resting heart rate and HRV, and significant negative correlation between Body Fat % and HRV in judo and wushu players.

OJC 2

Efficacy of Ayurvedic Science in the Fields of Sports

Akriti Sharma[1], Kirti Bhati[1]

[1]Department of Swasthavritta and Yoga, Bharati Vidyapeeth (Deemed to be University) College of Ayurved, Pune, Maharashtra, India

Ayurveda is an ancient medical science. It is very distinctive system of medicines with indomitable ideologies. As Ayurvedic system of medicines is so adaptable in nature and always trying to cope up with the problems arising in this modern world, with its traditional knowledge and distinctive methodology instigated in Samhitas. Ayurvedic practitioners are always eager to seek the knowledge from various different fields, to do something better for the mankind and Sports medicine is one of those fields that is becoming the new focus for the Ayurvedic practitioners by improving the performance of a sports person in their specific games with their traditional methods. In sports, health, physical fitness and mental fitness plays very essential role towards the performance of a sports person in their specific games. There are various procedures and formulations in Ayurveda that we can be indorsed in sports injuries or prevent them from injuries along with several daily and seasonal regimes to be adapted for the promotion of health of an individual including daily pathya ahara (nutritious diet), vyayama (physical exercise) according to the season, weight and strength of an individual person by increasing the endurance and stamina. Also, some Abhyanga (massage) techniques to strengthen the muscles or to relax the mind of a person. Medicated oils have healing properties, injuries which are musculoskeletal in nature can be healed with various techniques. Yogic and pranayam techniques help

for the cleansing of body and mind respectively. The main focus of this article is to acquaint with the efficacy of Ayurvedic (traditional) science in the fields of sports.

OJC 3

Estimation of Prevalence of Myocarditis in Athletes: A Systemic Review

Pratik Saha[1], Shrishti[1], Lakshmi Ramesh[1], Aparna Sarkar[1]

[1]Amity Institute of Physiology and Allied Sciences, Amity University, Noida, Uttar Pradesh, India

Background: Myocarditis is a leading cause of arrhythmias and sudden cardiac death (SCD) in physically active people and athletes alike. Elite athletes appear to be at an increased risk of viral infection and subsequent myocarditis due to increased pathogen exposure (global travel/international competition) or an inhibited immune system (continuing training during infections/resuming training soon after, strenuous exercise training). Athletes may be at a higher risk of adverse cardiac events. The initial clinical presentation varies, but athletes exhibit non-specific symptoms of fatigue, muscle soreness, increased heart rate at rest and during exercise, and decreased overall exercise capacity However (unnecessary) prolonged disqualification of athletes to avoid adverse cardiac events can cause significant disruption to training schedules and tournament preparation, leading to a decline in performance and ability to compete. As a result, improved risk stratification tools are critical. Among several diagnostic methods like ECG, Echocardiography and cardiac biomarkers, Cardiac magnetic resonance imaging (CMR) should be more focused upon.

Purpose: To assess and contrast the differences in existing recommendations and present a new proposed diagnostic process flow focusing on the use of cardiac magnetic resonance imaging in athletes with suspected myocarditis using the most recent available data,

Methods: A substantial number of correlated research papers were perused to ascertain the results. Furthermore, the availability of mundane information such as risk factor, inhibited immune response, diagnostic procedures was established via incisive analysis of pertinent websites.

Results: Based on scant evidence, primarily autopsy studies and expert opinions, current recommendations generally recommend a minimum of 3 to 6 months of abstinence from competitive sports for the prevention of onset of myocarditis among suspected athletes.

Conclusions: Due to the high level of cardiac stress in highly competitive sports, precise screening modalities are required, particularly for acquired cardiac diseases such as acute myocarditis. Evidence from large multicentre registries, including cardiac magnetic resonance imaging, is required to modify recommendations in athletes with myocarditis. A yearly follow-up examination should be performed on all athletes.

ABSTRACT

This chapter encompasses a detailed overview of recent trends in the synthesis of graphene-transition metal-oxide-based nanocomposites and their applications for the photocatalytic degradation of pollutants. The comprehensive case study of the synthesis of reduced graphene oxide (rGO)-TiO_2 nanocomposites for photocatalytic and sono-photocatalytic degradation of methomyl (carbamate group pesticide) has further thrown some more light on the topic.

Nanocomposites of transition metal oxides and graphene in the form of graphene oxide (GO) and rGO has gained lot of popularity because graphene can significantly enhance the photocatalytic activity of transition metal oxides. Graphene transition metal oxide nanocomposites mainly include composites viz. rGO/GO-TiO_2, rGO/GO-ZnO, rGO/GO-Fe_3O_4, rGO/GO-CuO, rGO/GO-V_2O_5, rGO/GO-Co_3O_4, rGO/GO-MoO_3, rGO/GO-ZrO_2 etc. They can be synthesized by using various methods viz. hydrothermal/solvothermal method, sol-gel method, in-situ deposition/chemical method, etc. The size, morphology, and photocatalytic activity of the nanocomposite is dependent on the method adopted for the synthesis of the nanocomposite.

Graphene-transition metal-oxide-based nanocomposites have witnessed tremendous applications in wastewater treatment. These nanocomposites have successfully degraded many types of organic pollutants, such as dyes, pesticides, and pentachlorophenols. Previous research reports and the case study presented have clearly indicated that these nanocomposites possess high photocatalytic activity as compared to bare transition metal oxides under both UV and visible light. The key beneficial effect of using graphene-based nanocomposites includes the availability of active sites in the form of functional groups useful for anchoring transition metal oxides. Apart from this, graphene can also act as an electron sink and, hence, lower the charge carrier recombination.

LIFETIME ACHIEVEMENT AWARD, 2020

CONFERRED ON

Professor Padmanabhan Balaram, FNA

Members of the Council and the Fellows of the Indian Chemical Society feel highly honoured to felicitate Professor Padmanabhan Balaram in recognition of his lifetime achievement in teaching and research in the field of Chemistry in general and Biological Science in particular.

Professor Balaram obtained Bachelor's degree in Chemistry from Fergusson College, University of Pune followed by Master's degree from the Indian Institute of Technology, Kanpur and PhD degree from Carnegie Mellon University with Aksel A. Bothner-By. During his PhD, Professor Balaram studied the use of negative Nuclear Overhauser effect signals as probes of macromolecular conformations. After a postdoctoral stint at Harvard University with Nobel laureate Robert Burns Woodward where he worked on the synthesis of the antibiotic erythromycin, Professor Balaram returned to the Indian Institute of Science, where he has rendered stupendous service till 2014. He is currently associated with the National Centre for Biological Sciences, Bangalore.

Early research of Professor Balaram focused on the membrane active peptide alamethicin, leading to a career long interest in the conformational restrictions on backbone folding promoted by the unusual residue alpha aminoisobutyric acid (Aib). The facile formation of 310-helical structures in Aib peptides was established by his studies in the late 1970s. His researches on the use of conformational constraints to direct peptide backbone folding led to the structural characterization of designed synthetic sequences that mimic secondary structures found in proteins. The use of D-Pro residues in nucleating beta hairpin formation, the design of multistranded sheets and the use of beta and gamma amino acid residues in generating hybrid helices were reported from his laboratory in the 1990s. His work on peptide design and analysis of protein structures has been of importance in the design of protein mimics. His laboratory was among the first to structurally characterise beta and gamma amino acid containing peptide structures in the 1990s, a key step in the development of the area of foldamers. His laboratory was also one of the first in India to apply the techniques of biological mass spectrometry in the area of protein chemistry.

The laboratory of Professor Balaram has contributed extensively to studies of the enzyme triosephosphate isomerase from plasmodium falciparum and more recently in the mass spectrometric and transcriptome based characterisation of peptide libraries from marine cone snail venom.

A dedicated academician, Professor Balaram has contributed significantly to the development of Chemical Education and Research in the country. Professor Balaram has built up a vibrant school of chemists and inspired a large number of students and colleagues who are carrying the torch of his mission.

The Indian Chemical Society sincerely wishes Professor Padmanabhan Balaram a long peaceful life with sound health and continuous academic activities for the advancement and propagation of scientific knowledge.

Indian Chemical Society

LIFETIME ACHIEVEMENT AWARD, 2020

CONFERRED ON

Dr. Jhillu Singh Yadav, FNA

Members of the Council and the Fellows of the Indian Chemical Society feel highly honoured to felicitate Dr. Jhillu Singh Yadav in recognition of his lifetime achievement in teaching and research in the field of Chemistry in general and Organic Chemistry in particular.

Dr. Yadav obtained Bachelor's and Master's degrees in Chemistry from Banaras Hindu University and PhD degree from M S University, Baroda. Dr. Jhillu Singh Yadav, CSIR Bhatnagar Fellow & former Director, Indian Institute of Chemical Technology (IICT), Hyderabad carried out extensive basic and applied research investigations in organic chemistry for the synthesis of over 190 complex natural products of biological relevance. Dr. Yadav specializes in the state-of-the art Asymmetric Synthesis to create new Chiral Centers. He extensively utilized them very effectively in the synthesis of drugs and agrochemicals having self-defensive properties against rice-blast disease, hypersensitive metabolites, anticancer, antibiotics and antifungal agents in a highly innovative manner. He excelled in creating and generating diverse chemical entities relevant to both agro and drug industry.

The insightful instincts of Dr. Yadav made him to foresee the versatility of insect sex pheromones in Indian agro-system. He pioneered the alternative eco-friendly and environmentally safe pest control technologies in India through the application of insect pheromones as major tools in Integrated Pest Management (IPM) for better and cleaner agro-products. His technology development efforts are highly commendable. Some of the drugs developed by Dr. Yadav have been well received by several Indian Industries like Diltiazem, Ketotifen, Mefloquin, Ondasetron (Cipla), Pyrazinamide (SPIC Pharma), Tamoxifin (Cipla) Misoprostol and Carboprost (AVRA Laboratories) etc.

Dynamic leadership of Dr. Yadav created and formulated many interdisciplinary programs at the Institute with the distinct aim to serve the nation. These have since established themselves as centers of excellence at the Institute. Dr. Yadav is an architect of distinction in building potential research groups with state-of-the-art facilities. He is an outstanding Organic Chemist of India. The Web of science (Science Citation Index) has referred him as the best and organic chemist par excellence in the country.

Dr. Yadav has the unique distinction of excelling in both basic and industrial research and received recognition accordingly. He is a fellow of The World Academy of Sciences (TWAS) for the advancement of science in developing countries and has received numerous national and international awards which include the prestigious, Shanti SwarupBhatnagar Prize, VigyanGauravSamman Award, Jawaharlal Nehru Science Award, Ranbaxy Award, Vasvik Award, Goyal Award, CSIR Technology Award, KIA Award (Iran-UNESCO). He is also the fellow of all the Indian Science Academies.

A dedicated academician, Dr. Yadav has contributed significantly to the development of Chemical Education and Research in the country. Dr. Yadav has built up a vibrant school of chemists and inspired a large number of students and colleagues who are carrying the torch of his mission. Two hundred and forty students have received their Ph.D degrees under his able guidance in Organic Chemistry. To his credit, he has more than 1200 scientific publications with 30000 citations and 140 patents.

The Indian Chemical Society sincerely wishes Dr. Jhillu Singh Yadav a long peaceful life with sound health and continuous academic activities for the advancement and propagation of scientific knowledge.

LIFETIME ACHIEVEMENT AWARD, 2020

CONFERRED ON

Professor Debashis Mukherjee, FNA

Members of the Council and the Fellows of the Indian Chemical Society feel highly honoured to felicitate Professor Debashis Mukherjee in recognition of his lifetime achievement in teaching and research in the field of Chemistry in general and Theoretical Chemistry in particular.

Professor Mukherjee obtained Bachelor's degree in Chemistry from Presidency College, Kolkata followed by Master's degree from the University of Calcutta and PhD degree from the Indian Association for the Cultivation of Science, Kolkata. Professor Mukherjee had joined the Indian Association for the Cultivation of Science in 1978, where he has rendered stupendous service till 2010.

Professor Debashis Mukherjee is presently the S N Bose Chair Professor in the S N Bose National Centre for Basic Sciences, Kolkata. He was previously the Director of the Indian Association for the Cultivation of Science (IACS), the Founder and the Chairman of its Raman Centre for Atomic Molecular and Optical Sciences and later the Emeritus Chair Professor.

Professor Mukherjee is a world leader in Theoretical Chemistry, well-known for his pioneering contributions in the field of molecular electronic structure and theoretical precision spectroscopy for electroweak interactions. His formulations of multi-reference coupled cluster formulations are regarded as pioneering and ground-breaking and are now standard works in the field. They are named after him. His cluster cumulant theories at finite temperature -- the corresponding Many Body Formalisms in Statistical Mechanics are also widely known and are increasingly being used in a wide variety of Statistical Mechanics problems.

Professor Mukherjee is the recipient of numerous awards and honors. He was awarded with the prestigious Humboldt Research Prize for his fundamental research in the many electron correlation problem. He is a Fellow of numerous International Academies, including the International Academy of Quantum Molecular Sciences (IAQMS), the World Academy of Sciences (TWAS), the Asia Pacific Association for Theoretical and Computational Chemists (APATCC), the Chemical Pioneer Award of the American Institute of Chemists, the Indian Academy of Sciences (IASc), the Indian National Science Academy (INSA) and the National Science Academy (NASI). He is also a S S Bhatnagar Prize Awardee. He was invited to deliver the Fukui Memorial Lecture as a Fukui Medal Awardee of the APATCC, and Coulson Memorial Lecture of the Center of Computational and Quantum Chemistry in the University of Georgia, Atlanta. He delivered the Jagdish Shankar and the SadhanBasu Memorial Lectures of the INSA.

A dedicated academician, Professor Mukherjee has contributed significantly to the development of Chemical Education and Research in the country. Professor Mukherjee has built up a vibrant school of chemists and inspired a large number of students and colleagues who are carrying the torch of his mission.

The Indian Chemical Society sincerely wishes Professor Debashis Mukherjee a long peaceful life with sound health and continuous academic activities for the advancement and propagation of scientific knowledge.

Endowment Lectures

Endowment Lecture

My experience of walking with crystals under UV light †

JJ Vittal
Department of Chemistry, National University of Singapore, SINGAPORE 117543
E-mail:jjvittal@u.nus.edu and chmjjv@u.nus.edu

Crystal engineering tools are successfully utilized to design crystals with desired physical and chemical properties, as these are directly related to their crystal structures.As more and more exotic new crystals are made, unexpected, unusual and unpredictable properties have been accidently discovered. For example, mechanically responsive materials were found to change their shape and size or move in space by light, thermal, pressure or chemical energy. Of these, dynamic molecular crystals undergo various movements like curling, crawling, jumping, leaping, hopping, popping, splitting, wiggling, and exploding, when exposed to heat (thermosalient effect) or light (photosalient effect). These photo-dynamic and thermal-dynamic crystals create new ways of transforming light and heat energy into mechanical work. In this context, we encountered a number of interesting properties such as structural transformations due to solvent exchange, change of composition and dimensionality due to grinding, unexpected photoreactivity of organic crystals and transition metal complexes due to [2+2] cycloaddition reaction, centrosymmetric MOFs showing second-order non-linear optical properties, chemical patterning in single crystals of MOFs,violent popping of single crystals under UV light (photosalient effect), thermosalient effect and photobending.In this talk some of these unusual properties of the crystals will be highlighted.

† Professor G. V. Bakore Memorial Award

Bio-data

JJ Vittal received BSc (University of Madras, 1975), MSc (Madurai University, 1977) and PhD from IISc, Bangalore (1982). After postdoctoral research work at the University of Western Ontario, Canada, he managed the X-ray facility for a few years. He then moved to Singapore in 1997 where he is a Professor of Chemistry at the National University of Singapore. He held a World Class University Chair Professorship at the Gyeongsang National University, South Korea (2009-2013). His recent research interests include various aspects of MOF materials, solid-state structural transformations and photochemical reactivity. He co-authored 'Crystal Engineering – A Textbook' and also co-edited two books on crystal engineering. He is a Fellow of Royal Society of Chemistry, Singapore National Institute of Chemistry and Indian Chemical Society. He won CRSI Medal (2020), Outstanding Chemist Award (2014), CRISP Award (2013), Outstanding Research Award (2011) and Best Scientist Award (2007). JJ has been highlighted in *Angewandte Author Profile* (2014). He founded the *Singapore National Crystal Growing Challenge* in 1997 to promote science through the art of growing crystals. He is an international committee member of Worldwide *IUCr Crystal Growing Competition for School Children* since 2014.

Design of nanostructured materials for photocatalysis and photoelectrochemical applications†

Ashok K Ganguli*, Anirban Das#, Saikumar Manchala and Shalini Tiwari
Department of Chemistry, Indian Institute of Technology Delhi, Hauz Khas, New Delhi 110016, India

Utilization of abundant sunlight for a more sustainable future of our civilization is the endeavour of the scientific community. One of the major requirementsfor achieving this is the development of catalysts that are able to utilize light radiation for chemical or electrochemical transformations. Broadly these catalysts are composed either of semiconducting materials or materials that exhibit surface plasmon resonance phenomenon. Nanostructured catalysts based on these materials are an important class of materials as their activity and selectivity can be tailored by variation of characteristics like size, morphology and aspect ratio.Our group has been very active in development of nanostructured photocatalysts[1-4] and photoelectrocatalysts[5,6]with controlled characteristics for the past two decades. We have utilized these materials for photodegradation of organic pollutants and photoelectrochemical splitting of water for production of clean fuels.This review presents a summary of the work carried out in our laboratory on development of photocatalysts and catalysts for photoelectrochemical applications.

Keywords: Photocatalysis; Photoelectrocatalysis; nanostructured materials; water splitting.

† Professor J. N. Mukherjee Memorial Award

Bio-Data:

Prof Ganguli did his B.Sc(Hons) Chemistry from Hans Raj College, University of Delhi, M.Sc (Chemistry) from University of Delhi and PhD in Solid State Chemistry from SSCU, IISc Bangalore in 1990. He carried out his post doctoral research at Dupont company USA and Ames Laboratory, Iowa State University, USA before joining IIT Delhi. Currently he is Institute Chair Professor of Chemistry and DeputyDirector, IIT Delhi. He is also the founding Director of Institute of Nano Science and Technology (Mohali). His main interest is in the area of design of materials, especially colloidal synthesis of nanomaterials and also in superconducting materials. He has published over 340 papers and has filed five patents (two granted). He is a recipient of the CRSI Bronze Medal(2006)& Silver Medal(2019), MRSI Medal(2007), National Award of Nano Science and Nanotechnology(DSTGovt. of India, 2015), Bangalore India Nano Award(Karnataka Govt, 2017) and the CNR Rao –CRSI National Prize of the Chemical Research society of India(2019), ISCB Award in 2019. He is a fellow of the Indian Academy of Sciences, National Academy of Sciences, India, Royal Society of Chemistry (London) and the Asia-Pacific Association of Materials. He is an Associate Editor of Bull. Mater Sci. and editorial board member of Chem Phys Letts, ACS Mater Letts and the J. Indian Chem. Soc. Dr. Ganguli is also a keen speaker for science in the rural & remote areasand has interacted with more than 320 schools/colleges in last seven years. Dr Ganguli is the coordinator of the Delhi S&T Cluster supported by the office of the PSA, Govt of India.

The Statistical Complexity Measure†

K. D. Sen
*School of Chemistry, University of Hyderabad, Hyderabad 500046, India*kds77@uohyd.ac.in

The product of an information theoretical measure of *order* with another exponential measure of *disorder* can be used to define a class of measures characterising the complexity of a given probability density distribution. Using the *statistical complexity measure* defined [1, 2] in the position space as $C_r = e^{Sr} D_r$, where $S_r$and $D_r$are Shannon information entropy and dis-equilibrium, respectively, along with its counterpart in the momentum space as $C_p = e^{Sp} D_p$, we demonstrate how such measures can be used to probe theelectronicstructureofatomsandmoleculesinwhichjusttheone-electron density is used as the key input parameter. The following four case studies[3-6] will be presented (*i*) the complexity of atoms in the periodic table (*ii*) thecomplexityofthegroundelectronicstateofhydrogenmolecularion(*iii*) complexity and the onset of Wigner crystallization of the confined pair of electrons,and(iv)aphenomenologicaldescriptionofathree-centrechemical insertion reaction.

Bio-Data:

Dr. K. D. Sen (PhD, IIT-Kanpur) F.A.Sc., F.N.A. joined University of Hyderabad in 1977 where he is now the senior most professor. His collaborative research in electronic structure theory with fellow scientists from Belgium, Cameroon, Canada, Chile, Germany, Greece, Japan, Mexico, Nigeria, Spain, Turkey, UK and USA has led to the publication of 8 monographs and 185 research papers. A recipient of Humboldt, Fulbright, and NSERC Canada Research Fellowship, he has been recently awarded the DAAD Research Professorship, Indo-US Professor of Physics of the American Physical Society and the J.C. Bose National Fellowship. International collaboration is his style of doing research since 1978.

Nanozymes and Nanoisozymes for Modulation of Cellular Redox Processes†

G. Mugesh
Department of Inorganic and Physical Chemistry
Indian Institute of Science, Bangalore
E-mail: mugesh@iisc.ac.in

Oxidative stress is caused by an imbalance between the production of reactive oxygen species (ROS) and the biological system's ability to detoxify these reactive intermediates. It is well known that oxidative stress is associated with diverse diseases, including cancer, renal disease, and neurodegenerative disorders such as Alzheimer's and Parkinson's disease. Antioxidant treatment has been found to be unsuccessful in many cases as they promote disease and increase mortality in humans. The reason for this unexpected behaviour is that antioxidants with strong reducing ability can act as pro-oxidants and increase the oxidative stress. Therefore, it is important to develop antioxidants without pro-oxidant activity. In this regard, our group is working on the design and synthesis of antioxidant enzyme mimetics such as small molecules and nanomaterials that can combat oxidative stress without affecting the cellular antioxidant systems. In this lecture, I will discuss our recent results on the development of nanozymes that can be used for cellular and biomedical applications.

Bio-Data:

Dr. Govindasamy Mugesh (born 1970) is an Indian inorganic and physical chemist, a professor and the head of the Mugesh Laboratory attached to the department of Inorganic and Physical Chemistry at the Indian Institute of Science. He is known for his studies on mechanism of thyroid hormone action and is an elected fellow of the Indian Academy of Sciences, Indian National Science Academy, Royal Society of Chemistry and the National Academy of Sciences, India. The Council of Scientific and Industrial Research, the apex agency of the Government of India for scientific research, awarded him the Shanti Swarup Bhatnagar Prize for Science and Technology, one of the highest Indian science awards, in 2012, for his contributions to chemical sciences. In 2019, he was awarded the Infosys Prize in Physical Sciences for his seminal work in the chemical synthesis of small molecules and nanomaterials for biomedical applications.

Crystal Engineering of Solid-state Pharmaceuticals: From Synthon to Salt-Cocrystal Drugs†

Ashwini K. Nangia

School of Chemistry, University of Hyderabad, India
ashwini.nangia@gmail.com

The subject of crystal engineering has grown from a fundamental understanding of hydrogen bonding, intermolecular interactions, supramolecular synthons, and crystal packing to improved pharmaceutical applications (1990 to 2015), and recently toward functional materials for sustainable energy, biomass valorization and solar cells as a new phase, coinciding with the oft asked question: what has science done for society lately?

The role of X-ray crystallography and crystal engineering in pharmaceutical development of new and improved medicines will be highlighted. The emphasis in these studies is to modify the physicochemical and pharmacokinetic properties of drugs as well as their crystalline forms to increase stability, solubility, and enhanced bioavailability. Other important properties which can be tuned for pharmaceuticals are permeability, half-life, color stability, cross reactivity for multi-drug compositions, tableting, compaction, etc. Three cocrystal-salt drugs have recently been approved by the US-FDA – Entresto (Valsartan-Sacubitril trisodium hemipentahydrate; Novartis), Steglatro (Ertuglifozin-5-oxoproline; Merck-Pfizer), and Suglat (Ipraglifozin-Proline; Astellas), as well as a few more drugs are in clinical and regulatory pipeline (Tramadol HCl-Celecoxib, Esteve; TAK020-gentisic acid, Takeda). The crystal engineering of multi-component cocrystals (ternary) offers the potential to arm multiple drug payloads in the same pharmaceutical composition.

† Rev. Fr. L. M. Yeddanapally Memorial Award

Bio-data :

Ashwini Kumar Nangia is a Senior Professor of Chemistry at University of Hyderabad. He completed MSc from IIT Kanpur (1983) and PhD from Yale University (1988). He started his professional career at UoH in 1989 as Lecturer and was promoted to Professor in 2002. His research group focuses on crystal

engineering topics – structure design, inclusion compounds, polymorphism, cocrystals, salts and eutectics, and the applications of these solid forms in pharmaceutical sciences for drug translation. He is a Fellow of three National Science Academies – INSA New Delhi, IASc Bangalore and NASI, Allahabad. He is recipient of the JC Bose Fellowship from DST. He was awarded the Golden Jubilee Commemoration Medal (Chemical Sciences, 2016) of INSA and the Prof. L. K. DoraiswamyChemcon Distinguished Speaker Award for 2016 by IIChE. He has international research collaborations with Russia, Singapore, UK and USA. He is on the Editorial Boards of subject journals, Crystal Growth & Design (ACS), CrystEngComm (RSC), Journal of Pharmaceutical Sciences (Wiley), Chemistry – An Asian Journal (Wiley-VCH). He was appointed Associate Editor of ActaCrystallographica, Section B, IUCr journals in 2017. He has published about300 papers in peer reviewed international and national journals, filed 15 patents, has H index of 60 and over 14,000 citations. He was awarded the Golden Jubilee Commemoration medal of INSA (2016) and Prof. D. N. Dhar Memorial lecture of NASI (2018). He was recently appointed Member of SERB Empowered Committee and as Adjunct Professor at ICT Mumbai (UDCT).

He is founder of spin off innovation and R&D venture Crystalin Research in 2010 under the banner "Chalk to Salt" at Technology Business Incubator facility on University campus. Crystalin Research completes a decade of successful functioning as a solid-state form modification and improvement venture in 2020. He was Director of CSIR-National Chemical Laboratory, Pune since March 2016 and completed his tenure successfully at the end of November 2020.

He was Chairman of India's first and largest Venture Center on NCL Innovation Park, co terminus with his tenure as Director, NCL. He re-joined University of Hyderabad as a Senior Professor of Chemistry in December 2020.

Perfecting Imperfections: Chemistry of Defects in Nanosilica for CO_2 to Fuel Conversion†

Vivek Polshettiwar

Nanocatalysis Laboratory, Department of Chemical Sciences, Tata Institute of Fundamental Research (TIFR), Mumbai, India.

Email: vivekpol@tifr.res.in, www.nanocat.co.in

Active and stable metal-free heterogeneous catalysts for CO_2 fixation are required to reduce the current high level of carbon dioxide in the atmosphere, which is driving climate change. In continuation of our work in the field of nanocatalysis,[1-13] recently we showed that defects in nanosilica (E'-centres, oxygen vacancies, and non-bridging oxygen hole centres) convert CO_2 to methane with excellent productivity and selectivity.[12]Neither metal nor complex organic ligands were required, and the defect alone acted as catalytic sites for carbon dioxide activation and hydrogen dissociation and their cooperative action converted CO_2 to methane. Unlike metal catalysts, which become deactivated with time, the defect-containing nanosilica showed significantly better stability. Surprisingly, the catalytic activity for methane production increased significantly after every regeneration cycle, reaching more than double the methane production rate after eight regeneration cycles. This activated catalyst remained stable for more than 200 h. Detailed understanding of the role of the various defect sites in terms of their concentrations and proximities as well as their cooperativity in activating CO_2 and dissociating hydrogen to produce methane was achieved.

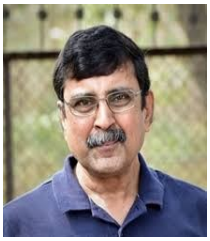
† Professor S. S. Sandhu Award

Bio-Data:

Prof. Vivek Polshettiwar, after his Ph.D. in 2005, worked as a postdoc in France and USA for few years before starting his own independent group at KAUST in 2009. In 2013, he moved to TIFR, and his group is working on the development of novel nanomaterials as catalyststo tackle “climate change”. He has published nearly 100 articles with h-index 54 and around 12400 citations in reputed journals like PNAS, Nature Comm, AngewChem, Chem. Sci., ACS Nano, ACS Catalysis etc. He is the recipient of the prestigious ORISE Research Fellowship at US-EPA. He was awarded as Top-25 cited author in 2011 by Tetrahedron and Young Scientist Award at DSL-2012. He also received an Asian Rising Star lectureship at 15th Asian Chemical Congress (ACC), Singapore (2013), from Nobel Laureate Professor Ei-ichi Negish. In 2015, he was admitted as a Fellow of Royal Society of Chemistry (RSC), United Kingdom. He was awarded Bronze medal by Chemical Research Society of India (CRSI), India. He was also recognized as emerging investigator-material science and 175 faces of chemistry by RSC, UK.He was awarded the prestigious Materials Research Society of India - MRSI Medal 2019 and Fellow Maharashtra Academy of Sciences. In 2020, he received Young Research Awards in Nano Science & Technology by DST, Gov. of India.

Ultrafast Pump-Probe and Single-Particle Photoluminescence Studies of the Caesium Lead Halide Perovskite Nanocrystals†



Anunay Samanta
School of Chemistry, University of Hyderabad, Hyderabad 500046
(anunay@uohyd.ac.in)

The lead halidebased perovskite nanocrystals have generated considerable interest in recent years because of their great potential in photovoltaic and photonic applications.[1,2] An understanding of the photo-induced processes in these systemsis key to proper utilization of these materials in different applications. In this talk, we shalldiscuss how femtosecond pump-probe and single-particle fluorescence based techniques can provide information on the identity and energy states of the photogenerated species,pathways and dynamics of relaxation of the charge carriers, location and nature of the trap states and their role in fluctuation of the photoluminescence of various caesium lead halide ($CsPbX_3$) perovskite nanocrystals.[3-7]

† Acharya J. C. Ghosh Memorial Award

Bio-Data:

Anunay Samanta is a Senior Professor and Dean of the School of Chemistry at theUniversity of Hyderabad. He joined here in 1990 after obtaining his Ph.D (1987) from IACS (Jadavpur University)and a postdoctoral tenure of little more than two years at the Radiation Laboratory, University of Notre Dame, USA. He has supervised the PhD thesis of 23 students, published 190 papers, which have been cited 9700 times.He is Fellow of all three National Science Academies of India and recipient of many national and international awards such as J.C. Bose National Fellowship, Thomson Reuters India Citation Award, Raman-Mizushima Lecture Award, and APA Award. His current research interests are ultrafast dynamics and single-molecule fluorescence spectroscopy of the perovskite nanocrystals and related materials.

Progress in CO_2 Utilization:from homogeneous to heterogeneous catalysts†

Francis Verpoort[1,2]

[1]State Key Laboratory of Advanced Technology for Materials Synthesis and Processing,

Wuhan University of Technology, Wuhan 430070, China.

[2]Center for Environmental and Energy Research (CEER), Ghent University Global Campus, 119 Songdomunhwa-Ro, Yeonsu-Gu, Incheon 406-840, South Korea

E-mail: Francis.verpoort@ghent.ac.kr

With modern industrydevelopment, carbondioxide (CO_2) has attractedmore and moreattentionasitsunignorableinfluence on thegreenhouseeffect. While in theaspectofsyntheticchemistry, CO_2isconsideredas an ideal C1 source foritsmerits, such asnontoxicity, economy, renewability, and abundance. Based on this, thetransformationof CO_2intoorganicsusinghomogeneouscatalystshasbecome a highly promising area in modern green and sustainablechemistry. Up tonow,numerousstrategieshavebeendevelopedtoeffectivelyutilize CO_2forthesynthesisofvaluablechemicals[1-6]. Moreover, also heterogeneous catalysts are intensively investigated for the utilization of carbon dioxide, especially Metal-organic Frameworks. Metal-organic frameworks are non-conventional porous materials having a broad spectrum of applications. The catalytic use of MOF-based materials is cutting-edge in the field of scientific and technological developments. Recently, MOFs are being investigated as promising catalysts for synthesizing of industrially important cyclic carbonates under solvent-free ambient conditions. A wide variety of terminal and internal substrates are converted efficiently with high selectivity. MOFs as heterogeneous catalysts are remarkably stable and have structural rigidity, hence recycled for subsequent use with almost the same activity. Therefore, MOF-catalysts are highly efficient for the cycloaddition of CO_2 to epoxides into cyclic carbonates[7-12].

Reaction of phosphoric acid mono aryl esters with a divalent metal such as Zn^{2+} in a donor solvent (L) leads to the isolation of tetranuclear metal phosphates $[(RO)PO_3Zn(L)]_4$ whose inorganic core resembles the zeolitic D4R SBU.[1-4] In recent times, we have also unravelled that it is possible to isolate even larger SBUs through small variations in the reaction conditions.[5] On the other hand the reaction of phosphoric acid mono and dialkylesters yield either 1-D polymers or 2-D materials which thermally anneal to produce ceramic materials at temperature lower than 300ºC.[6] Rationalization of these building principles will be presented in this lecture, apart from highlighting the use of this class of compounds as molecular magnets,[7] phosphorus based perovskites,8 and energy related materials.[6]

Ramaswamy Murugavel received his B.Sc. and M.Sc. degrees from University of Madras and Ph.D. from IISc. He carried out postdoctoral work at the University of Göttingen (1994-1997) and joined the chemistry faculty of IIT Bombay in December 1997, where he is currently the Biswas Palepu Distinguished Chair Professor and a J C Bose National Fellow. He is a fellow of the Indian Academy of Sciences, the Indian National Science Academy, and the Royal Society of Chemistry. He has been conferred with J. C. Bose National Fellowship, Swarnajayanti Fellowship, Alexander von Humboldt Fellowship, DAE-SRC Outstanding Investigator Award, DFG Mercator Professorship, C. N. R. Rao National Prize in Chemical Sciences, S. C. Bhattacharya Award for Excellence in Research in Basic Sciences, DAE Young Scientist Award, CRSI Bronze and Silver Medals, MRSI Medal, and J. C. Ghosh Medal. His research work has been published in the form of 200+ publications.

Diheme Enzyme *Mau G*: Our Understanding towards Nature's Design †

S. P. Rath*

Department of Chemistry, Indian Institute of Technology Kanpur, Kanpur-208016,

e-mail: sprath@iitk.ac.in

MauG is a terminal enzyme involved in the biosynthesis of the catalytic tryptophan tryptophenylquinone (TTQ) cofactor of methylamine dehydrogenase (MADH). Although two heme units are physically separated in the enzyme, they share electron efficiently behaving as a single diheme unit. A tryptophan residue, positioned midway between the heme centers, has been postulated to act as a bridge for electronic communications. *MauG*-catalyzed TTQ biosynthesis is accomplished through radical chemistry and initiated using H_2O_2 as the oxidant which produces bis-Fe(IV) redox state (Figure 1). As the two hemes are physically separated by 14.5 Å, a hole-hopping mechanism has been proposed in which the tryptophan residue reversibly oxidized and reduced during electronic communication. These attractive features have prompted us to investigate on such diheme enzyme and the results will be highlighted in the talk[1,2].

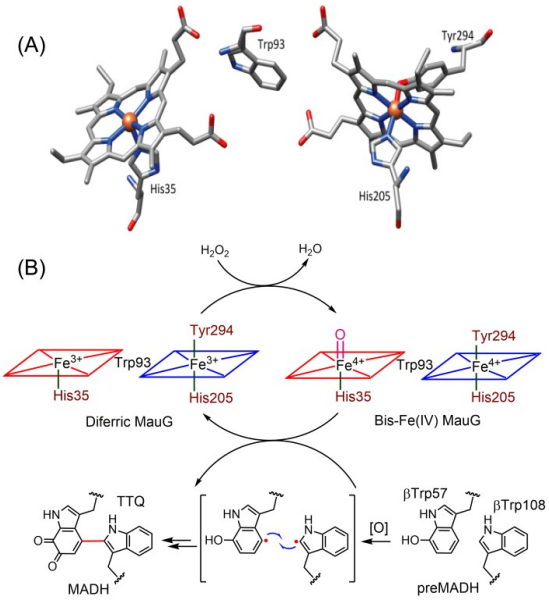

Figure 1. (A) Relative orientation of hemes and the intervening tryptophan residue in *MauG* (PDB ID code 3L4M). (B) Overall biosyntheis of TTQ catalysed by *MauG*.

Awards & Honours:

- SERB - Science and Technology Award for Research (SERB-STAR), 2020
- Fellow, Indian Academy of Sciences, Bangalore, 2020
- J. N. Gupta & M. Gupta Chair Professor, IIT Kanpur (2017-2020)
- JSPS Invitational Fellowship, Japan, 2020
- Professor R S Varma Memorial Award by Indian Chemical Society, 2020
- C. N. R. Rao National Prize in Chemical Sciences, 2018
- Fellow, National Academy of Sciences, 2017
- Bronze Medal, Chemical Research Society of India (CRSI)- 2015
- Fellow, West Bengal Academy of Science & Technology, 2017
- Institute Foundation Day Lecture, NIT Patna on January 27, 2017
- Alexander von Humboldt Research Fellowship for Experienced Researcher in 2012
- P. K. Kelkar Faculty Research Fellowship from IIT Kanpur (2009-2012)

Research Details

The family of multiheme proteins constitutes one of the most fascinating molecular machineries designed by Nature to execute a large variety of functions. The functional properties of such important and widely distributed family are largely determined by the arrangement and interaction of their multiple heme cofactors. Rath's group is pioneer in the biomimetic study of this important class of proteins and contributed significantly in understanding Nature's sophisticated design in modulating structure and properties viz., metal spin and electronic state, reactivity, rate of electron transfer, redox potential etc., of the individual heme centre.

Supramolecular chirogenesis is one of the most important interdisciplinary fields to be looked into because of its occurrences in many natural and artificial systems. Rath's group has also contributed significantly in understanding the origin and various aspects of chirality induction, control and amplification at the molecular level.

Current research interests include investigating Multi-heme Proteins & Enzymes, Bio-inorganic Chemistry, Chemical Biology, Medicinal Inorganic Chemistry, and Supramolecular Chirogenesis.

Coherency of Recent Trends in Organic and Medicinal Chemistry†

Asit K. Chakraborti*
Department of Chemistry, IIT-Ropar, Punjab
Formerly at Department of Medicinal Chemistry, NIPER,S. A. S. Nagar, Punjab
(e-mail: chakrabortiak@iitrpr.ac.in; akchakraborti@niper.ac.in)
Homepage: http://akcresearchgroup.weebly.com/

While the pharma sector had been deliberating for long on the requirements of knowledge base and experimental skill that a medicinal chemist should possess it is well accepted that organic synthesis remains at the core of the activities of drug discovery program.[1] Thus, any advancement in the area of organic synthesis is expected to enrich the synthetic tool box of medicinal chemists. In recent times sustainability has been the yardstick of the modern developments of organic chemistry resulting enrichment of the synthetic tool box of medicinal chemistry[2] in compliance with green chemistry principles.[3] However, while the modern development of organic chemistry should obviously expand the medicinal chemistry synthetic tool box[4] these newly developed synthetic methodologies are rarely observed in the discovery medicinal chemistry.[5] This results in over dependent on the existing structural framework narrowing the chemical space and hence the scope of IP (Intellectual Property). Thus, a coherent approach encompassing the recent trends in organic and medicinal chemistry is advocated for sustainability in drug discovery research.[6] The present discussion would address the integration of sustainable development of organic chemistry[7] with drug discovery for generation of new therapeutic leads[8] and optimization.[9]

† Professor P K Bose Memorial Award

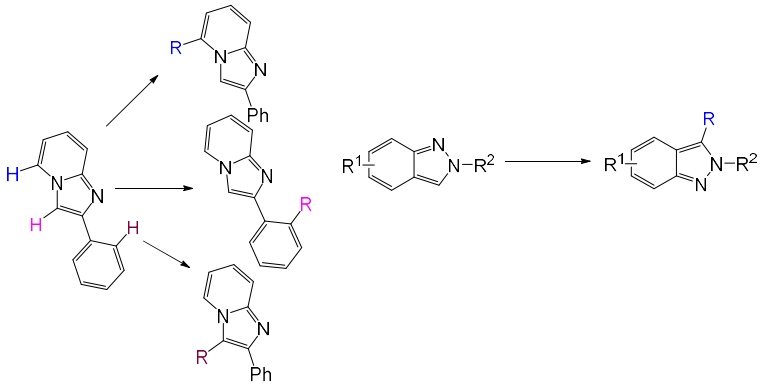
Bio-Data:

Professor Chakraborti received Ph. D. degree in Synthetic Organic Chemistry from IACS, Kolkata in 1985 and post-doctoral research training in USA: department of Chemistry, Clemson University (1985-1987) and Medicinal Chemistry, Purdue University (1987-1989).He served Burdwan University (WB) as lecturer of Chemistry (1990-1994) and NIPER-Mohali, Punjab as Assistant Professor (1994-1999), Associate Professor (1999-2001), and Professor (2001-2019) of Medicinal Chemistry. He has guided 40 Ph. D. and 130 Masters' students, published 180 research papers (> 10,000 citation, h index 61), filed 42 patents. He received University Gold Medal, Bardhaman Sammilani Gold Medal, ISMAS Eminent Mass-spectroscopist award, Ranbaxy Research Award (Pharmaceutical Sciences), CRSI Bronze Medal, R V Patel PharmInnova Best Research Guide Awards for "Innovative Ph. D. Thesis" (2017-2018 & 2016-2017) and "Innovative MS Thesis" (2015-2016 &2014-2015) in "Pharmaceutical Chemistry." He is Fellow of Royal Society of Chemistry, Indian Academy of Sciences, Bangalore and Indian National Science Academy, New Delhi.

Regioselective C−H Functionalization of Indazoles and Imidazopyridines†

Alakananda Hajra*
Asst. Professor of Chemistry
Visva-Bharati University, West Bengal
e-mail: alakananda.hajra@visva-bharati.ac.in
Web: http://vbchem.ac.in/AlakanandaHajra/

Heterocyclic compounds have gained a great deal of attention as majority of the drugs contain heterocycle scaffolds. So the developments of new synthetic strategies for heterocycles are prime targets of the organic chemists over the years. Imidazopyridine is one of the important fused bicyclic 5–6 heterocycles and it is recognized as "drug prejudice" scaffold due to its wide applications in medicinal chemistry. This scaffold is the constituent of various marketed drug like zolpidem, alpidem, zolimidine, necopidem, saripidem etc. In this lecture I will discuss our recent works on sustainable synthesis of imidazo[1,2-a]pyridines,[1,2] and indazoles[3].



Scheme 1. Regioselective functionalization of imidazopyridine and indazole

† Professor Dhananjay Nasipuri Memorial Lecture

Bio-Data:

Dr. Alakananda Hajra graduated (M.Sc) from the Department of Chemistry, Indian Institute of Technology, Kharagpur India in 1998. After completing his Ph.D in 2002 under the supervision of Prof. B. C. Ranu from Indian Association for the Cultivation of Science (IACS), Kolkata he joined in SUNY at Albany, USA as a postdoctoral research fellow with Prof. Frank M. Hauser (2002-04). He was also a JSPS research Fellow in the University of Tokyo and worked with Prof. Eiichi Nakamura and Prof. Masaharu Nakamura from November 2004 to May, 2006. He also worked with Prof. N. Yoshikai, NTU, Singapore for one year (2011-2012) as a visiting scientist. His research interests are the development of new synthetic methodologies and green synthetic procedures. He has published more than 167 peer-reviewed articles with more than 6700 citations, giving him a h-index of 42.

Awards / Honors / Membership:

- Professor D Nasipuri Memorial Award for the year 2019 by Indian Chemical Society
- Chemical Research Society of India (CRSI) Bronze Medal Award for the year 2018
- Prof. D. K. Banerjee Memorial Lecture Award for the year 2015 from Indian Institute of Science

Quantum chemistry from molecules to materials†

Sourav Pal*

Indian Institute of Science Education and Research Kolkata

Mohanpur, Nadia- 741 246, West Bengal, india

Clusters play an important role in understanding the transition from atomic and molecular systems to the nano-scale systems. Different types of clusters display interesting bonding and properties. In this presentation, we will describe our research on bare as well as doped gold and aluminum clusters on oxidation reactions, di-nitrogen and C-X bond activation. In particular, we noted the potential of Al-clusters on BN-doped graphene. Density functional theory has been used to obtain the results and insights into the functional clusters. Both periodic calculations based on plane wave basis and molecular model calculations using Gaussian basis sets have been used for our calculations.

*Formerly: CSIR-National Chemical Laboratory, Pune 411 008, India

†Professor A K Chandra Memorial Award

Bio-Data:

Prof. Sourav Pal is presently Director of Indian Institute of Science Education and Research (IISER) Kolkata. He was formerly the Director of CSIR-National Chemical Laboratory (NCL), Pune and worked at NCL Pune for almost 33 years. He was also a Professor of Chemistry at IIT Bombay. He was instrumental in setting up Electronic Structure Theory Group at NCL He is a distinguished theoretical chemist and has contributed to methodological and conceptual developments on many-body electronic structure theory, to the area of density based chemical reactivity as well as to catalytic and hydrogen storage materials using computational material science.

He obtained his 5 years' integrated Master's degree in Chemistry from Indian Institute of Technology (IIT) Kanpur in 1977, received Ph.D. degree from Calcutta University and joined NCL in 1982. He was a post-doctoral fellow at the University of Florida, Gainesville, USA (1986-87) and has been Alexander von Humboldt Fellow at the University of Heidelberg, Germany (1987). He was been visiting Professor abroad at the University of Arizona, Tucson, USA, University of Torun, Poland and the Institute for Molecular Sciences, Okazaki, Japan. He also holds Adjunct Professorship at IISER Pune and IIT Goa. He is also distinguished Visiting Professor at IIT Kharagpur.He served as the President of Chemical Research Society of India for three years from April 1, 2014. He is a member of Executive Council of Federation of Asian Chemical Societies and is Chairman of Chemical Division Council of Bureau of Indian Standards. He is also a member of Board of the newly set up Commonwealth Chemical Sciences In addition, he has served in several important scientific committees in the country. He is presently a member of the Council of Indian National Science Academy, New Delhi.

He has been recognized by several awards and honors for his contributions to science, including the prestigious Shanti Swarup Bhatnagar Award in Chemical Sciences in 2000 and SASTRA-CNR Rao Award in Chemistry & Materials Science for the year 2014, among others. He is a Fellow of The Indian National Science Academy (2003), Indian Academy of Sciences (1996) and National Academy of Sciences (1998), Royal Society of Chemistry (2011) and the Maharashtra Academy of Sciences (1994). He is J C Bose National Fellow of Department of Science and Technology from 2008. He is presently a member of the Council of Indian National Science Academy.

Heis presently in the EditorialAdvisory Board of the Journal of Physical Chemistry, has guided more than 40 Ph D theses and has published more than 280 papers in International peer reviewed journals. He has authored a book titled "Mathematics in Chemistry" and contributed to chapters in several books. He has been invited to deliver plenary / keynote / highlighted lectures in several institutions and international conferences of repute over the years.

Isomerization Reactions in Anionic Mesoionic Carbene-Borates and Control of Properties and Reactivities in the resulting CoII Complexes through Agostic Interactions

Biprajit Sarkar

Stuttgart University, Germany

biprajit.sarkar@iac.uni-stuttgart.de

Mesoioniccarbenes (MICs) of the 1,2,3-triazol-5-ylidene type are important ligands in organometallic chemistry and catalysis. Most MICs of this type are neutral ligands. Cationic MIC ligands remain relatively rare, and there are very little known about anionic MIC ligands. In this contribution, we will report on bidentate and anionic borate-based MIC ligands. A unique C-N isomerisation reaction in these ligands will be discussed. We will present Co(II) complexes with these isomerized ligands in which the geometry, the spin state, and the reactivity of the metal center can be controlled throughagosticinteractions in the secondary coordination sphere of themetal center. Results from synthetic chemistry, NMR spectroscopy, single-crystal X-ray diffraction, single crystal EPR spectroscopy and theoretical calculations will be discussed.

† Professor R. D. Desai 80th Birthday Commemoration Award

Bio-Data:

Biprajit Sarkar studied chemistry at the University of Delhi and at IIT Bombay before moving to Stuttgart, Germany to work on his PhDwith Prof. W. Kaim. After his PhD he moved to Strasbourg, France as a post-doc in the group of Prof. P. Braustein. Between 2006 and 2011 Biprajit was a „Habiltand“ (Asst. Prof.) at the University of Stuttgart, and between 2012 and 2019 he was an Associate Professor at the Free University Berlin. Since October 2019 he has been full professor and chair of inorganic coordination chemistry at the University of Stuttgart. His research interests are in the fields of redox-active ligands, carbenes, catalysis and switchable molecular materials. Biprajit has published morethan 300 papers in peer-reviewed international journals, and currently servesas a sectioned it or forthe Encyclopedia of Inorganic and Bioinorganic Chemistry.

Invited Lectures

Opportunities, Limitations and Recent Advances in Ionic Liquids as Environmentally benign Solvents for Chemical and Technological Applications

Ramesh L. Gardas
Department of Chemistry, Indian Institute of Technology Madras, Chennai 600 036, INDIA.
Phone: +91 44 2257 4248; E-mail: gardas@iitm.ac.in; Web: http://chem.iitm.ac.in/faculty/gardas

Chemistry is dominated by the research on different kinds of solution to understand the behaviour of molecules in the solution phase and in molecular solvents. Any liquid may be used as a solvent but quite few are in general use. Solvents are major contributors and high on the list of environmental damage chemicals, mainly because of their large usage and high volatility. The widespread use of volatile organic compounds (VOCs) in many industrial chemical processes is an issue of great environmental concern. It is an extremely important task to search of potentially green and environment friendly alternatives for VOCs. At least a partial solution to this problem may offer by a novel class of molten salts referred to as ionic liquids (having melting point, generally, below boiling point of water), as they possess unique combination of particular properties, unlike molecular liquids, namely negligible vapour pressure (~ 10^{-11} to 10^{-10} bar at room temperature), wide thermal window (~ -50 °C to +250 °C), wide electrochemical window (~ ±3 Volt vs. NHE), non-flammability, high ionic conductivity and a highly solvating capacity for organic, inorganic and organometallic compounds. This unique combination of particular properties leads them to be exploited as "green solvents" and giving them increasing attention in academic and industrial research. The research areas on ionic liquids are growing very rapidly and the potential application are numerous, mainly due to the fact that simple changes in the cation and anion combinations or the nature of the moieties attached to each ion allow the physical properties of ionic liquids such as hydrophobicity, viscosity, coordinating ability, ion selectivity, and chemical and electrochemical stability to be tailored for specific applications. Proposed talk will include the introduction of green solvents, ionic liquids, and current research trends on ionic liquids as green solvents for the chemical and technological applications.

Bio-Data:

Dr. Ramesh Laxminarayan Gardas promoted to Associate Professor in July 2015. Ramesh Laxminarayan Gardas was born and brought up in Surat, Gujarat. He completed B.Sc., M.Sc. and Ph.D. in Chemistry from the Veer Narmad South Gujarat University. Then he joined University of Coimbra and University of Aveiro, Portugal, and Queen's University Belfast, UK for his postdoctoral research on physico-chemical properties and applications of ionic liquids. Then, Dr. Gardas joined the Indian Institute of Technology, Madras, India, in August 2010, as an Assistant Professor in Chemistry, and to full Professor in March 2020.

Dr. Gardas has more than 20-years of research and 10-years of teaching experience. So far, he completed 8 projects (as PI and Co-PI) worth more than Rs. 6.5 crores, guided 11 Ph.D. and 15 M.Sc. project students. Co-authored 4 patents, 4 book-chapters, 7 conference papers and 160 research publications

which received more than 6100 citations with h-index = 38 and average citations per paper of above 38. He delivered more than 150 invited talks and guest lectures.

Dr. Gardas' research group focusses on 'Chemical Thermodynamics' and 'Phase Equilibria' of industrially important solvents and their mixtures. His research group, is unique in the country, focusses on both 'Science' and 'Technology' part of contemporary field – "Ionic Liquids/ Deep Eutectic Solvents as alternative to Volatile Organic Solvents" and significantly contributing in connecting them. His research group substantially contributed to the development of non conventional and environmentally benign solvent systems. Generated extensive databases on their thermodynamic properties and structure-composition-property correlations useful in refrigeration, separation science and crude oil industry. These will have far reaching implications in the design of application-specific solvent systems. His research group strives to design the task specific ionic liquids and to provide an important insight into physical chemistry to regulate their properties for varied technological applications such as phase change materials, CO_2 capturing, dissolution of tank bottom sludge, electrolytes in solar cell and super capacitors, absorbents for refrigeration system, desulfurization of fuels, and also extraction of metal ions, biomolecules and value-added products.

More than 7500 thermodynamic data points measured in his research lab at IIT Madras are included in NIST Standard Reference Database developed by Thermodynamics Research Center, NIST, USA. Dr. Gardas developed a model to explain the density of a variety of ionic liquids over a wide range of temperature and pressure which is referred to and extensively used by the peer scientific community as 'Gardas and Coutinho' model.

In recognition of his outstanding performance as a researcher, Dr. Gardas has been bestowed with several awards by prestigious institutes/ societies including the Mid-Career R&D Award-2020 by IIT Madras. Recently, he has been recognized as (i) Associate Editor of Heliyon, Elsevier journal, (ii) Fellow Royal Society of Chemistry (FRSC), UK, (iii) Publons Top Peer Review Award 2019 (Top 1% of Reviewers in Chemistry), and (iv) one among the world's top 25 'Emerging Investigators' by the Journal of Chemical and Engineering Data, an American Chemical Society Journal.

Analysis of Respirable Crystalline Silica

Archana Saily Painuly
Research and Development Division
ADE Consulting Group, Melbourne, Australia
archana.painuly@ade.group
archanasailypainuly@gmail.com

Exposures to respirable crystalline silica has many adverse health effects especially to people who works in mines and construction sites.Recommended exposure limit is 0.05mg/m^3as a time weighted average for up to 8 hours/day during a 40-hour workweek. A variety of methods /instruments are available for its determination. Current techniques used for respirable silica are FTIR and XRD.The present talk will be on the comparison of the two XRD method- US NIOSH and UK MDHS based on time, use of chemicals, accuracy and efficiency. US NIOSH filter redeposition filteration method is quite common using XRD, however, method is quite lengthy and tedious. UK method based on direct analysis on filters using XRD is not only time saving but also environment friendly. Dust generator designed for present method is efficiently deposited crystalline silica on filters and straight to the instrument for quantitative analysis against standards. Result outcome shows that UK MDHS method using dust generator provide accurate and precise results in a short span of time and uses no other chemicals except standards, make it environment friendly technique.

Bio-Data:

Dr. Archana Saily Painuly is an Alumni of IIT Roorkee, India and UWS, Australia. She has more than 20 years of experience in quality control analytical and environmental research labs in various capacities both in Australia and overseas. She has an expertise in method development and method validation for NATA and ISO 17025 accreditation for environmental analyses using major analytical instruments. She has immense experience related to NAAC accreditation for higher education institutes of northern part of India.

Her research covers broad spectrum of hydrometallurgical and bio-metallurgical methods with interest from basic mechanism to industrial applications. She has developed cost effective green methodology for recovery of heavy and hi-tech metals.

Dr. Painuly has three Patents to her credit on development of processes for the recovery of hi-tech and strategic metals from low grade ores, spent catalysts and industrial wastes. She is recipient of SEEWRT Research Award by UWS, Sydney and AINSE Award by ANSTO, Sydney to study the metal speciation and geochronology in sediment cores of lake Burragorang. She also received research award from Indian Society of Analytical Scientist, India for her work on removal and recovery of molybdenum and tungsten from wastes. She has been Executive Editor of Journal of Environmental Science, Toxicology and Food Technology since 2012. She currently serves as associate editor, guest editor and editorial board members and reviewers for several International and National journals. Currently she is involved in developing methods for airborne pollutants, soil hazardous contaminants and acid sulphate soils.

Studies of selenium and its species using instrumental, preconcentration and radiochemical neutron activation analysis

A. Chatt
Trace Analysis Research Centre, Department of Chemistry, Dalhousie University
6274 Coburg Road, Room 212, PO BOX 15000, Halifax, NS, B3H 4R2, Canada
E-mail: a.chatt@dal.ca

Selenium has long been recognized as an essential trace element. Inductively coupled plasma mass spectrometry (ICP-MS) and neutron activation analysis (NAA) are widely used for its determination. We have taken advantage of the unique features of NAA such as its ability to analyze a few milligrams of solid as well as liquid samples non-destructively and independently of chemical species, and to determine low levels of selenium with excellent precision, accuracy, sensitivity, and detection limits in developing several NAA methods for assaying selenium and its species in a variety of materials.In instrumental NAA (INAA), the long-lived radionuclide ^{75}Se (half-life = 118.5 d) is generally used whichrequires lengthy irradiation, decay and counting schemes. Instead we have developed several methods including cyclic INAA (C-INAA) and pseudo-cyclic INAA (PC-INAA) for the detection of the short-lived nuclide ^{77m}Se (17.5 s) using both thermal and epithermal neutrons followed by conventional and anti-coincidence (PC-INAA-AC) gamma-ray spectrometry for the rapid measurement of picogram levels of selenium in milligram amounts of biological materials with high precision and accuracy.We have also applied these INAA methods in combination with solvent extraction for the simultaneous measurement of low levels of inorganic Se(IV) from Se(VI) selenium species and its co-contaminants such as arsenic and antimony species in natural waters. We have used a PC-INAA-AC method for measuring ppb levels of selenium in infant formulae and baby foodsand compared the results with a RNAA method for reliability, rapidity, sensitivity, and expanded uncertainty. Details of the methods and their applications will be presented.

Bio-Data:

A. Chatt received his Ph.D. in nuclear analytical chemistry from University of Toronto, Canada. He was a Full Professor and Killam Professor of Chemistry, Director of SLOWPOKE-2 Reactor facility, and presently an Adjunct Professor at Dalhousie University, Canada. Professor Dr. Chatt supervised 21 PhD, 17 MSc, 68 BSc students, and 75 postdoctoral fellows. His research interests include development of nuclear analytical and speciation methods. He has published over 190 papers, and presented over 465 invited papers. He is a Fellow of American Nuclear Society and Chemical Institute of Canada. He received many awards including the most prestigious international award in nuclear and radiochemistry called the Hevesy Medal Award. He is Associate Editor of Journal of Radioanalytical and Nuclear Chemistry. His professional activities include serving as a scientific expert for IAEA in more than 12 countries. He served as the President of International Committee on Activation Analysis over a 20-year period.

The application of thermoanalytical methods in the investigation of biologically important systems

Sinjan Choudhary
UM-DAE Centre for Excellence in Basic Sciences, University of Mumbai,
Vidyanagari, Mumbai 400098, India

Thermal analysis covers a group of techniques in which a property of the sample is monitored against time or temperature while the temperature of the sample is programmed. In the past few decades, the application of thermoanalytical methods has been extended to the investigation of several types of naturally occurring compounds of biological origin. Thermodynamic analysis of biologically important molecules deals with structural insights and stability studies. It also helps to understand specific and nonspecific macromolecular recognition occurs in biologically important processes. Thus, thermodynamic studies provide an amply of information which is not only of fundamental scientific interest but also of enormous practical applications in biotechnology, pharmaceuticals and drug design. Calorimetry is a thermoanalytical method which directly and quantitatively measures the parameters associated with macromolecular stability and recognition. Structural transitions, like protein folding-unfolding, intermediate state formation and nucleic acid melting can be studied using differential scanning calorimetry (DSC). Ligand–protein, protein-protein, DNA-protein binding interactions can be studied by using isothermal titration calorimetry (ITC). DSC provides precise information on the extent of stabilization or destabilization provided by solvent/co-solutes along with the determination of thermodynamic parameters such as ΔHo, ΔSoand ΔGoof unfolding. The heat capacity of denaturation of the proteins in absence and in presence of different ligands/solvents will provide a quantitative information on the conformational details in combination with spectroscopic measurements. The experimental data obtained from ITC is used to obtain the values of enthalpy of binding (ΔHo), entropy of binding (ΔSo), binding constant (K), Gibbs free energy of binding (ΔGo), and binding stoichiometry. Such quantitative details of interactions of ligands with the proteins provide insights into the groups involved and the forces involved in the molecular recognition process. Thermo-analytical approach is widely being used for obtaining insights into biomolecular stability and mechanism of biomolecular interactions.

Bio-Data:

Dr. Sinjan Choudhary is currently working as Assistant Professor in the Department of Chemistry, UM-DAE Centre for Excellence in Basic Sciences, Mumbai. She obtained her M.Sc. in Biotechnology (2008) from Jawaharlal Nehru University, New Delhi and a Ph.D. in Biothermodynamics and Biophysical Chemistry (2012) from Indian Institute of Technology Bombay, Mumbai. Dr. Choudhary performed fundamental work in Biophysical characterization of protein-solvent and drug-protein interactions and protein folding intermediates using combination of spectroscopy and calorimetry during her Ph.D. Subsequently, she joined UM-DAE Centre for Excellence in Basic Sciences, Mumbai for her postdoctoral studies (2013-2015). As a postdoctoral fellow she was involved in structural characterization of ribosomal proteins from different parasites using different biophysical techniques. She started independent research work on „inhibition of protein fibrillation by small molecules‟ which was supported by DST-SERB Early Career Research Award. Her research work has been published in various reputed international journals. She has also been inducted as Editorial Board Member of Journal of Chemical Thermodynamics. She is recipient of various awards such as “Professor Shantilal Oswal Young Scientist Award” and “Giauque Memorial Award” in recognition of the research work in Thermodynamics and Bioenergetics. Dr. Choudhary‟s current research group is involved in unraveling the mechanism of inhibition of protein fibrillation and aims to exploit natural plant product based therapeutics for prevention of Parkinson‟s Disease. She has obtained SERB funding both at earlier career level and as core research grant.

Actinide ion extraction using room temperature ionic liquids: Understanding the mechanism for fuel cycle applications

P. K. Mohapatra
Radiochemistry Division, B.A.R.C., Trombay, Mumbai-400085, India.
Email: mpatra@barc.gov.in

Nuclear power is fast emerging as the suitable alternative energy source to the popular fossil fuel based energy sources. However, the public acceptance of nuclear power largely depends on the mitigation of the long term hazards of the radioactive wastes emerging out of spent fuel reprocessing. Studies on the extraction of actinide ions from radioactive feeds have great relevance in nuclear fuel cycle activities, mainly in the back end processes focused on spent fuel reprocessing and waste management. The recovered actinides can find many applications and hence, are termed as 'wealth from waste' in a true sense. Though traditionally, molecular diluents have been used for reprocessing and waste management activities in the nuclear industry, recently the room temperature ionic liquid (RTIL) based diluents are becoming increasingly popular and hence, needs to be evaluated thoroughly.

The chemistry of the actinide ions is quite fascinating in view of their unique properties such as simultaneous existence in multiple oxidation states, autoradiolysis, large alpha activity associated, etc. Therefore, the extraction of actinides in RTIL based solvent systems due to complex extraction mechanisms makes it a challenging area of research.

By the suitable tuning of the cationic and anionic parts of the ionic liquids, their physical properties such as density, dielectric constant and viscosity can be changed which are considered key parameters in the extraction of the actinides. Aqueous solubility of the RTILs, which can lead to significant solvent loss, can be avoided by appending the extractant moieties onto the ionic liquid, termed as Task Specific Ionic Liquids. While the low vapour pressure and non-flammability of the ionic liquids make them appear as 'green' diluents, their aqueous solubility raises concerns of environmental hazards.

The lecture gives a summary of studies carried out on actinide ion extraction and presents perspectives of its applications in the nuclear fuel cycle with a brief discussion on the mechanism of extraction.

Bio-Data:

Dr. P. K Mohapatra joined Radiochemistry Division, BARC in 1887 after graduating from the 30th Batch of the BARC training school. An Alxander von Humboldt Fellow during 1998-2000, his research interest indude separation of actinides and fission products using novel extractants, in ionic liquid based solvents and novel separation techniques including liquid membranes. In view of his excellent contribution to separation science and technology, he has been elected as an honorary Fellow of National Academy of Sciences, Allahabad. A recognized guide of Mumbai University and Homi Bhabha National Institute (Deemed University), Dr. Mohapatra is an associate Editor of Separation Science and Technology and one of the Editors of Radiochimica Acta. He is also Editorial Board member of several International journals. Currently, he is heading actinide chemistry section and has over 370 publications in peer reviewed International journals.

Advances in Instrumental Analysis - Academia and Industry

Dr. Ajit Datar
datarajit1949@gmail.com

It is over last 70 years; the Instruments for Chemical Analysis are being used. The instruments used for analysis improved very rapidly from where it started to where it is today. Lot of the credit goes to overall development in instrumentation, electronics and computer technology including both hardware and software.

There are five important 'S' of analytical chemistry and all the development of analytical instrumentation, which has happened is around these 'S'. These 'S' are:

Sensitivity Selectivity Separation Structure Speed

In this lecture we will talk about how these 'S' have influenced the development of Analytical Instruments. It was realized that there are three factors; which are necessary to be suppressed to get required precision and accuracy of analysis. These three factors are Sampling error, Background and Noise. The effect of these errors is understood and the development has happened to reduce the effect of these factors. Biological Science is in the fore front and analytical instruments are being developed for analysis of biological samples. Under the current pandemic situation, it is of more importance. The term Omics has been used to get more information of biological system. In addition to

Genomics, Transcriptomics, Proteomics, Lipidomic, there is a new omics called as metallomics. The importance of metal ion and its valence state is getting realized in biological cells. The importance of ICP-MS, Speciation techniques are being used to identify the metallic elements in biological samples.

There are some more areas of concern, like miniaturization, more automation and the process analyser (PAT- Process Analysis Technology). Lot of development is happening in these areas.

The Analytical Instrument Lab in any research institute and in Industry is unfortunately considered as a service provider and there is a belief that there is not much scope of research in the field of analytical chemistry.

As the world of Analytical Instrument is advancing, we need to analyse the situation in which we are. There are three points of a triangle, one is Instrument manufacturers, the other Industrial users and the third is Academic users. The Instrument manufacturers are very well connected with both the users. The users are hardly connected with each other and that is why there is a gap between the Industry and academia.

There are many examples where the academia developed a prototype instrument and transferred the technology to the instrument manufacturer for developing a commercial product.

However, there is a need to develop skills which are required by Industry. We have to change. We have to introduce the syllabi considering the need of Industry and provide hands on training to the students by having some key instruments in the post graduate labs.

At the end, I would like to conclude that we have to get ready for the new generation of analytical instruments, with propre training at the college levels so that skilled man power can be developed for quality research and for the Industry which is striving for the trained man power.

I would like to advice my student friends that they should add skills to the basic qualification. Along with skill development, the students should also have self-development attitude for accomplishing best out of their aptitude.

Bio-Data:

Ajit Ganesh Datar has just retired as an Advisor to Shimadzu Analytical India Pvt. Ltd., Mumbai in the Customer Support Centre. His main job profile was to provide instrumental analysis support to the customers and provide training. Prior to Shimadzu, he was with Thermo Electron and served this organization as General Manager, Advanced Mass Spectrometry. He was responsible for promoting advanced Mass Spectrometry products of Thermo Finnigan in India. He retired in 2007 after completing 58 years. He served for Chromline and IR Technology as Technical Direcor and Sr. Manager respectively for period of 15 years. His first assignment was with Central research Station of Associated Cement Cos Ltd as Research Officer. He served ACC for 12 years. He has developed methods for characterization of catalysts and process products using catalysts. He indigenously developed BET Surface Area Analyser and particle size analyser.

Dr. Datar received his M.Sc. in 1971 and Ph.D. in 1976 from Mumbai University. He was recipient of Department of Atomic Energy Fellowship in 1971 and carried out his Ph.D. research from Analytical Chemistry Division of BARC.

He is a visiting faculty at several colleges in Mumbai. He has several publications in his name and was a guide for Ph.D. in Mumbai University and guided 8 students in the period of 2009 to 2017.

Functional Nanocomposite Materials based Electrochemical Bio-Sensors

A. K. Srivastava
Department of Chemistry, University of Mumbai, Vidyanagari, Santacruz (E), Mumbai, India
Email: aksrivastava@chem.mu.ac.in

The growing variety of sensors has significant impact on everyday life with increasing demand for minimal costs and potential for real time monitoring. Considering these developmental factors, electrochemical approaches are the most promising due to their simplicity, miniaturization, high sensitivity and specificity. Functional nanocomposite materials have proved valuable in advancing the field of electrochemical sensors. The research in the field of functional nanocomposite materials based electrochemical sensors has earned an exceptional prominence in the recent years, as it has wide applications in clinical diagnostics and biological research. Various kinds of functional nanocomposite materials including carbon based nanomaterials, metal and metal oxides nanoparticles, conducting polymers, metal organic frameworks and / or macrocyclic compound have recently been employed by my research group for the development of electrochemical sensors. Their synergistic effect is found to be highly useful for the sensing of various classes of drugs such as alkaloids, analgesics, antipyretic, antibiotics, etc. at ultra trace level in pharmaceutical and biomedical samples[1-3]. Efficient enantiorecognition of enantiomers is of enormous importance in optically active pharmaceuticals products for effective and safe therapy.

Recently, Enantioselective analyses of multi-chiral drugs were investigated on nanocomposits modified electrodes with chiral selectors based on host-guest interactions employing differential pulse voltammetry[4,5]. This talk will describe some of our recent research on the application of functional nanocomposites for the development of electrochemical biosensors.

Dr. A. K. Srivastava is a former Professor of Analytical Chemistry at the Department of Chemistry, University of Mumbai. He did his M.Sc. and Ph.D. in Analytical Chemistry from Banaras Hindu University in 1976 and 1981 respectively. He was a visiting professor at Michigan Technological University in 2006 and has been a visiting scientist at the US Army Research Laboratory, Aberdeen, USA intermittently during 2006 - 2018. He has guided 10 M.Sc. by Research, 28 Ph.D. and 4 Post-doctoral students. His research projects were funded by UGC, DST, BRNS-DAE and US Army research Laboratory mainly in the areas of Chromatography, Electrochemical (bio) sensors, Energy Materials, etc. He has over 150 publications in high impact international journals and have received over 4300 citations with h-Index of 35.
It is creditable that he has been declared as ‘author with highest number of citations’ in the field of Analytical Chemistry, which earned him the ‘Thomson Reuters Research Excellence India Citation Award – 2015’. He received the ‘Best Teachers Award by Government of Maharashtra and is a elected ‘Fellow of the National Academy of Sciences, India’.

Current Status of Atomic/Chemical Studies of Heavy and Trans- Actinide Elements at JAEA

Tetsuya K. Sato
Advanced Science Research Center, Japan Atomic Energy Agency

The chemical and atomic properties of heavy elements with atomic numbers greater than 100 are attracting an interest; their properties are affected by strong relativistic effects, and advanced techniques of analytical chemistry are required to conduct experiments at an-atom-at-a-time scale.

Recently we have successfully measured the first ionization potentials (IP1) of the heaviest actinide elements, fermium (Fm, atomic number Z = 100), mendelevium (Md, Z = 101), nobelium (No, Z = 102), and lawrencium (Lr, Z = 103) by using a novel method based on surface ionization technique[1,2]. The measured lowest IP1 value of Lr among those of actinides corresponds that Lr would have a loosely-bound electron in the outermost orbital. The comparison of the experimental value and the value predicted by the relativistic calculations strongly suggested that the electronic configuration of the Lr atom would be different from that predicted from the periodic table.

Besides, we also investigated the adsorption properties of volatile compounds of dubnium (Db, Z = 105) on a quartz surface. Adsorption enthalpies of oxychlorides of group-5 elements have been measured[3]. The results show that the volatility of Db oxychlorides could be almost similar to or lower than that of tantalum compounds.

At the presentation, recent activities about studies on atomic and chemical properties of the heaviest elements at JAEA will be introduced. Future experimental plans would be presented as well.

Bio-Data:

Dr. Tetsuya K. Sato obtained his Ph.D. (Science) from Niigata University in 2003. In the same year, he joined the Japan Atomic Energy Research Institute (JAERI, current Japan Atomic Energy Agency (JAEA)). For his significant contribution in nuclear chemistry, he was awarded the prize from Japan Society of Nuclear and Radiochemical Sciences in 2019.

Neutral, Hydrophobic Fluorescent Probes and their Bio-analytical Applications

Anil K Singh
Formerly Professor, Department of Chemistry, Indian Institute of Technology Bombay, Powai, Mumbai – 400 076; *(E-mail*: retinal@chem.iitb.ac.in)

Fluorescent probes are molecular entities used in several sophisticated analytical techniques of spectrofluorimetry. From bioanalytical perspective, these probes are used in probing structure, biomolecular binding and interactions, cellular events and dynamics, analysis of drugs and pharmaceuticals, new drug discovery and cellular drug tracking, environmental monitoring, high precision quantification of biomolecules, etc. These probes can be broadly categorized as: i) intrinsic probes- based primarily on biomolecules like the amino acids, proteins, and antibodies and, ii) extrinsic probes- derived mainly from synthetic molecules, select biological proteins, and quantum dots. In certain situations, these probes suffer from a few disadvantages. For instance, unsuitability of biomolecular intrinsic probes may be due to probe's inadequate fluorescence efficiency, wavelength range, sensitivity and, ability to provide proper information in the presence of multiple fluorophores in the system. Similarly, a biological extrinsic probe like a protein may be unfit due to its generally large molecular size, artifactual response, andphotoinstability.

Due to these limitations, small organic molecules-based extrinsic probes have been developed, which are derived from molecules like acridines, anthraquinones, benzoxathioles, coumarins, cyanine dyes, fluorescein, naphthalene, oxadiazoles, pyrenes, tetrapyrroles, triarylmethanes, xanthenes, etc. However, in many applications, even these probes are found to be inadequate due to their shorter absorption and emission wavelengths, hydrophilic and self-ionic behaviour, etc. While the shorter wavelength renders the probes unfit for biological and medical applications, the self-ionic/charged character contributes towards unwanted ionic/secondary Columbic interactions between the probe and the host system. Such interactions interfere with the fluorescence studies and complicate fluorescence data interpretation.

Considering the aforesaid, attempts have been made to develop neutral, hydrophobic fluorescent probes based on linear small molecules containing >C=C< chromophore. Generally, such molecules are either non-fluorescent or fluoresce inefficiently due to excited state energy dissipation through C,C double bond isomerization. However, it has been found that linear molecules of diarylpolyene series can fluoresce quite efficiently and can be used as neutral, hydrophobic probe in several fluorescence-based analyses. These molecules exhibit dual fluorescence involving locally and conformationally relaxed intramolecular charge transfer states. The emission from these states can be modulated considerably, with solvent and substituent. Further, in the solid state, these molecules can exhibit aggregation-induced enhanced fluorescence due to specific molecular arrangement in the crystal. Also, remarkably enhanced fluorescence is observed from their nanoparticles. The fluorescence probe efficacy of these molecules is demonstrated by studies of the microenvironment of organized assemblies and proteins. Attempts have also been made to develop two-photon excitable molecules, which owing to lower energy of employed

photons, cause less photo-damage and photo-bleaching to the host systems than the corresponding one-photon fluorescence microscopy. Such fluorochromes have brought new dimensions to fluorescence probing, wherein lies a great scope for exploring their bioanalytical applications.

Bio-Data:

Prof. A. K. Singh, a former Professor of Chemistry at the Indian Institute of Technology (IIT) Bombay embodies wealth of expertise and experience in science education and research, policy formulation, and administration. During a career spanning over four decades, Prof. Singh has worked in several key capacities in IIT Bombay and participated in drawing-up and developing academic policies and programs of education and research, and expansion of collaborations both in India and abroad.

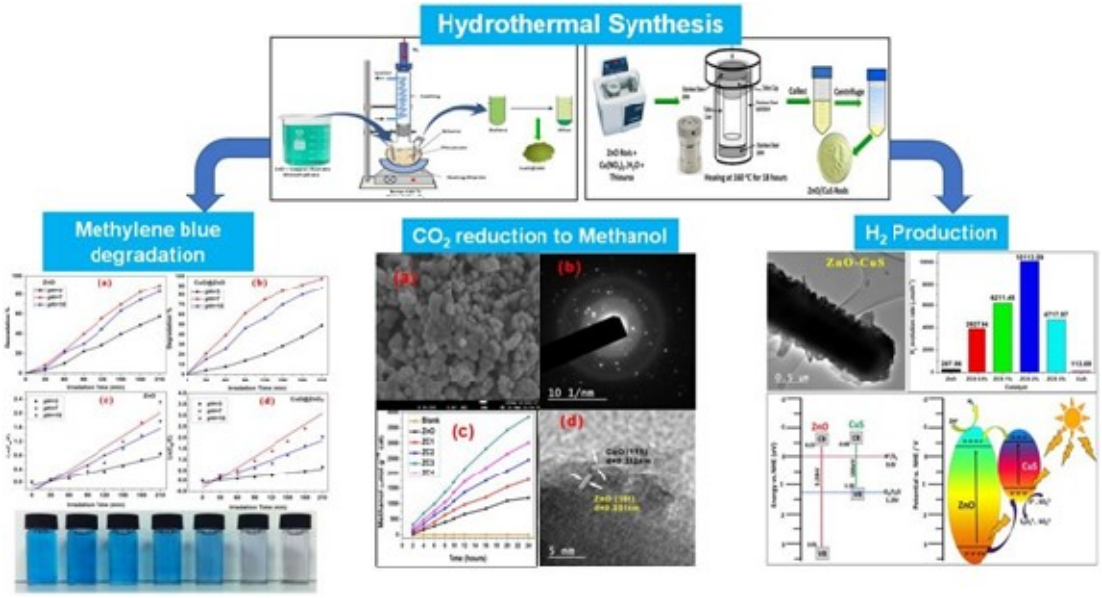
He has also been associated in multiple capacities with several national and international educational and research institutions, R&D organizations, prestigious science academies and professional societies, government bodies, administrative and policy making entities etc., to drive organizational excellence. He has also held the position of Director, CSIR-Regional Research Laboratory (present-day North-East Institute of Science and Technology) Jorhat; and, Vice-Chancellor of two major universities, the Bundelkhand University and the University of Allahabad (a Central University). He is currently appointed as Independent Director of Rashtriya Chemicals and Fertilizers Ltd. Mumbai – a Government of India Undertaking, Ministry of Chemicals & Fertilizers.

Prof. Singh's research interest has been multidisciplinary in nature, broadly spanning the areas of organic and bioorganic chemistry, photochemistry and photobiology, with particular focus on: i) developing molecular understanding of structure and mechanism of functions of photoreceptors involved in biological sensory (e.g. vision) and energy (e.g. proton-pump) transductions, ii) excited state chemistry of linear polyenes, iii) photochemical synthesis, iv) design and development of novel molecular entities. His endeavours and contributions are duly recognized by the academic and research organizations, government and corporate bodies, prestigious science academies and professional societies, by awards and honours.

Modified ZnO - Synthesis, Characterization and Catalytic Applications

Dr. B. Sreedhar
Senior Principal Scientist Analytical and Structural Chemistry Division
CSIR - Indian Institute of Chemical Technology Hyderabad - 500 007, Telangana

Development of an efficient, stable, economically viable and eco-friendly photocatalysts for hydrogen production has become a major objective in chemistry and a promising avenue to overcome the global energy crisis. In the present work results of the synthesis, characterization and application of nanostructures - ZnO-CuO, ZnO@CuS and ZnO@ZnS-NiS2 are discussed for the degradation of methylene blue, hydrogen production and CO2 reduction to methanol. All the three composites were synthesized by a simple hydrothermal method and well characterized by XRD, FE-SEM, TEM, XPS, UV-Vis-DRS, photoluminescence and hotoelectrochemical studies.



- ZnO@CuO hybrid nanocomposites demonstrated higher degradation activity for methylene blue (5 ppm) of 98% (pH 7), 49% (pH 3) and 87% (pH 10), photocatalytic H2 production rate of 4604 µmol h-1 g-1 and high efficiency for photoreduction of CO2 to methanol inaqueous solution containing dimethylformamide (DMF) and triethylamine (TEA) as electron donor under visible light irradiation.

- Synergistic effect of CuS and ZnO in ZnO@CuS nanorods resulted in increased light harvesting capability and efficient charge separation during the photocatalytic process leading to remarkably high photocatalytic H2 production (10113.59 µmol•g−1h−1) and an apparent quantum efficiency of 22.3% that is nearly ~35 times as high as that of pristine 287.96 µmol•g−1h−1.

- Three-component ZnO@ZnS@NiS multijunction photocatalyst exhibited higher hydrogen evolution activity (140.3 µmol g−1) under simulated solar light irradiation in 4 hrs, far exceeding those of bare ZnO (1128 µmol g−1), ZnO@ZnS (1808.8 µmol g−1) and ZnO@ZnS@NiS (8471.1 µmol g−1) counterparts.

This work provides a facile, controlled method for the fabrication of multicomponent heterostructures used for efficient solar water splitting. In addition to morphological properties, materials properties like surface area, active sites (vacancies, grain boundaries, corners and edges, unsaturation coordination), surface interface reaction are the major influencing factors. Various experimental parameters such as the effect of solution pH, type of sacrificial agent, and catalyst loading have been found to be very crucial that greatly affect the photocatalytic activity.

He has 379 Papers published in National and International Journals, 06 US patents and 143 papers presented in National and International Conferences. There are 8 Ph.Ds awarded and 2 ongoing; 45 M. Tech Project works and 75 M.Sc Project works under his guidance.

Occurrence and Potential Health Impact of Phthalates in the Environment

Prof. Fiona Regan
School of Chemical Sciences,
Dublin City University, Glasnevin, Dublin 9

Phthalate esters are synthetic organic chemicals used in many consumer products including cosmetics, toys, flooring and medical devices, and are ubiquitous within the environment (Gao and Wen, 2016). Humans are constantly exposed to phthalates, with increasing evidence of detrimental health effects (Ejaredar et al., 2015; Jurewicz and Hanke, 2011; Polańska et al., 2016). The European Commission is preparing to amend the Authorisation List (Annex XIV to REACH) with the additional identification of four phthalates as substances of very high concern (SVHCs) with endocrine disrupting effects on human health or the environment (European Commission, 2015). The phthalates in question are bis(2-ethylhexyl) phthalate (DEHP), dibutyl phthalate (DBP), benzyl butyl phthalate (BBP) and diisobutyl phthalate (DiBP). Other phthalates have yet to be studied extensively, and it is predicted that these replacement phthalates may prove to be as dangerous as those under legislative control.

This study examined eleven phthalates in a range of Irish environmental matrices. A novel triple-quad LC-MS method was developed with optimisation of sample preparation (SPE and US). The examination of phthalate burden in Ireland has shown that levels in Ireland are consistent with those reported elsewhere in Europe. Concentrations ranged from N.D. to 95 µg/L in aqueous samples and 0.01 to 315.21 µg/g in solid samples, with DiBP and DBP as the most prolific phthalates. Soil was identified as the largest sink of phthalates in our environment. A wastewater epidemiology approach was employed to assess human exposure to phthalates via measurement of phthalate metabolites. Exposure modelling determined that exposure in Ireland was below regulatory limits, and consistent with previously reported levels. A meta-analysis related the level of exposure to an associated risk, providing the first step in phthalate risk assessment within the Irish environment. This will close the knowledge gap from lack of biomonitoring data and inform future policy.

Design and Control of Magnetically Tunable Colloidal Materials

Prof. Sibani Lisa Biswal
William M. McCardell Professor in Chemical Engineering
Rice University, Houston, TX

One of the most exciting areas in colloid research is the control of interparticle interactions to generate new structures. The ease of tuning interactions, size, shape and composition has made these nano- and micrometer sized particles appealing probes for a number of fundamental studies. Recent work has focused on the use of colloidal particles that can act as models for studying the fundamental phenomena of atomic systems. The self-assembly of these "colloidal atoms" has led to investigations of the dynamics of chemical transformations such as nucleation or phase transitions. I will describe the application of a unique colloidal assembly system, with an isotropic interaction potential, to study material properties, such as phase transitions and melting. Magnetic filaments comprised of magnetic particles linked with DNA offer a method to probe dynamics of semiflexible filaments.

Additionally, studies on out of equilibrium phenomena will offer novel dynamic behavior, such as colloidal microscale swimmers. Our results promise to open up new insights into magnetically actuated 2-D materials.

Bio-Data:

Dr. Sibani Lisa Biswal is Professor and Associate Chair in the Department of Chemical and Biomolecular Engineering at Rice University in Houston, TX and leads the Soft Matter Engineering Laboratory. She has a B.S in chemical engineering from Caltech (1999) and a Ph.D. in chemical engineering from Stanford University (2004). She is the recipient of an ONR Young Investigator Award (2008), a National Science Foundation CAREER award (2009), Rice U. Graduate Student Association Faculty Teaching and Mentoring Award (2012), the George R. Brown Award for Superior Teaching (2015), the Rice University Chemical Engineering Alumni Professional Progress Award (2017), and the SW American Institute of Chemical Engineers Best Applied Paper Award (2018).

Particle size analysis of colloidal materials by scattering techniques

P. A. Hassan
Head, Nanotherapeutics and Biosensors Section, Chemistry Division, Bhabha Atomic Research Centre, Trombay, Mumbai-400 085 Email: hassan@barc.gov.in

Colloids comprising metals, semiconductors, polymers, surfactants, lipids etc have become an important component in several emerging technologies. Scattering of light, x-rays, neutrons etc have played a key role in understanding the microstructure, size distribution and short range order in such colloidal suspensions. In particular, several nano formulations have been employed by pharmaceutical and cosmetic industries for effective delivery of active ingredients. Recent studies indicate that drug delivery systems employing such colloidal carriers enhance the efficacy, minimise toxicity or even open new treatment modalities thereby leading to improved therapeutics. The average particle size, size distribution, shape and stability of the colloids are important parameters that dictate the efficacy of the formulation. This lecture highlights the application of scattering techniques for ensemble averaged morphological analysis of colloidal suspensions.

Bio-Data:

Dr. P. A. Hassan joined Bhabha Atomic Research Centre (BARC), Mumbai in 1993 and presently serving as Head of Nanotherapeutics and Biosensors Section, Chemistry Division, BARC. He was a visiting researcher at the University of Louis Pasteur, Strasbourg, France in 1995. He pursued his post-doctoral research at the Department of Chemical Engineering, University of Delaware, USA in 2000-2002. He has visited advanced neutron scattering facilities like National Centre for Neutron Research, NIST, Maryland, USA and Institute Lau Langevin, Grenoble, France. He has co-authored more than 140 papers in peer-reviewed journals with a total citation of 5600 and h-index 41 (google scholar). His current research interests include microstructure and dynamics of self assembly, polymers, polyelectrolyte-surfactant interactions and nano drug delivery systems. He is an elected fellow of the National Academy of Sciences, India.

The Saha Institute of Nuclear Physics-University of Calcutta collaboration - an example of many models of analytical chemistry

Susanta Lahiri
Saha Institute of Nuclear Physics, 1/AF Bidhannagar, Kolkata-700064 2 Homi Bhabha National Institute, Anushakti Nagar, Mumbai, 400094
E-mail: susanta.lahiri@saha.ac.in

The scientific discipline analytical chemistry is the science of many models. This statement has two aspects, first, the analytical chemistry is enriched by the contribution of many fundamental scientific branches, which is obviously true. Today's analytical chemistry has been shaped by the principles of physics, chemistry, mathematics, statistics, engineering, etc. The second aspect is that the analytical chemistry helps to unravel the puzzle of other scientific branches.

For last two decades the Radioanalytical Chemistry and Trace Analysis laboratory of Saha Institute of Nuclear Physics is enormously collaborating with various departments of the University of Calcutta, like Department of Archaeology, Department of Biotechnology, Department of Botany, Department of Chemistry, Department of Environmental Science, Department of Marine Science, etc. These collaborations resulted excellent outcome[1-11]. Apart from University of Calcutta, we had also nationwide inter-disciplinary collaboration with other premier institutes and universities like, Department of Physics, Indian Institute of Technology Roorkee, Department of Physics, Department of Chemistry and Department of Geology, Punjab University, Department of Chemistry, Department of Biological Sciences, Indian Institute of Science, Education of Research, Department of Chemistry, Indian Institute of Engineering, Science and Technology, Department of Microbiology, University of Sikkim, etc. Analytical Chemistry played crucial role in all of these interdisciplinary collaborations and have high output.

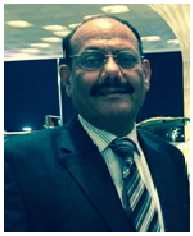
Bio-Data:

Professor Susanta Lahiri is an eminent radiochemist of International fame. He has made pioneering contributions in heavy ion assisted production of clinically important radionuclides. However, his interest has also proliferated in the areas of environmental radioactivity, green chemistry, cosmochemical analysis, bioaccumulation studies, speciation studies, as well as trace analysis. Currently he is working as Senior Professor at Saha Institute of Nuclear Physics, Kolkata, India. He received a doctorate degree from the University of Calcutta in 1994 and the University of Calcutta conferred upon him a D.Sc degree in 2009.

Professor Lahiri received the highest international honour in the field of Nuclear and Radiochemistry, the Hevesy Medal Award in 2015 and became the first Indian to receive the award in the history of ~50 years. The award was instituated in 1968 in honour of Nobel Laureate George de Hevesy. Earlier he received the prestigious associateship of Third World Academy of Sciences (TWAS) twice. He also received Professor J. C. Ghosh Memorial Award (2014) by Indian Chemical Society.

Professor Lahiri is the editorial board member of Journal of Radioanalytical and Nuclear Chemistry and Radiochimica Acta. He is also the member of CERN MEDICIS programme. He has more than 230 publications in international peer reviewed journal and 300 reports in international and national conference. He has guided 13 Ph. D students.



Analysis of functional foods

Balasaheb K Deshmukh
BKD Consultants, Carlsbad, CA 92010, bkd51@yahoo.com

Inclusion of function enhancing foods in the diet is a current trend and nutritional necessity. Various plant bioactives (bioactive peptides, botanicals), antioxidants, dietary fibers, functional starches, prebiotics, probiotics, functional lipids, vitamins, minerals, and other dietary supplements, and functional beverages, are few of the functional foods being used by consumers. Most of these foods may follow GRAS (generally regarded as safe) standard and do not go through the approval and scrutiny like a pharmaceutical material. As consumptions of these foods have increased exponentially, many customers and food formulators want to include these additives on the Nutritional Label. Because of rampant use, there is demand for stricter regulations for transparency and claims of the functionality of these additives. Unlike, pharmaceutical actives, there is not a well established path to register and scientifically certify the claims of functional foods. Many ethical producers of the functional foods establish their own analytical protocols to certify the content and functionality of the additives in the formulated foods. This also provides a commercial edge to the ethical manufacturers,

Development of a protocol for known additives, involves use of established methods, recommended by AOAC or other certifying bodies. These methods and protocols may work or need modifications to apply to new formulated products. When a new functional food is formulated with new additive, then there is a strong need to have new protocol. The new protocol involves a development of a procedure, validation of the method in the formulation and conducting Inter Laboratory Uniformity (ILU) tests. For uniform applicability of the protocol, it is advantageous to have an approval of reputable technical body. During the presentation, I will discuss an example of a new dietary fiber. The discussion will cover, defining needs, selecting technology, development of analytical procedure, validation and ILU studies and approval of method by AOAC.

Bio-Data:

Dr. Balasaheb Deshmukh is alumnus of Nagpur University Nagpur. He received his PhD from Nagpur University. He also served as a lecturer at Nagpur University Dept. of Chemistry before moving to University of Pittsburgh Pennsylvania. Later, in Pennsylvania and in New Mexico, he worked on National Science Foundation and National Institutes of Health funded research programs in the areas of ion selective electrodes, lithium ion batteries and cardiovascular drugs. He joined R&D of The Dow chemical Company in 1990 and carried out work in the areas of dielectric materials, cleaners, food additives, controlled release of drugs, and dietary fibers etc. As a Senior Research Leader he led various groups undertaking analyses of polymers, additives, bio molecules, agricultural products, solar cells, surfactants, solvents and process analyses. He has written book chapters on analysis of dietary fibers, published reviews and 52 research articles. He has presented his research work in more than 50 international conferences. He lives in California, USA.

He is a National scholar, received NSF and NIH research awards and was nominated for Harvey Wiley award by AOAC International. He was a BD Tilak Visiting Professor at Institute of Chemical Technology Mumbai 2007. He is also an Ex President of Analytical Sciences Discussion Group, Midland, Ex President Sigma Xi Scientific Research Society Midland Chapter Life member Indian Chemical Society, Member American Chemical Society Member Bioactive Lipids Society, Member Electrochemical Society.

Applying Different Analytical Approaches to Understand Intermolecular Interactions of Therapeutic Agents with Biological Receptors

Dr. Neelima Gupta
Centre of Advanced Study, Department of Chemistry &
DIC-RU, Centre for Converging Technologies,
University of Rajasthan, Jaipur
E-mail: gupta_neelima@uniraj.ac.in

Drug-target interactions are basis for any therapeutic effect of drug candidate. Drugs interact with biological molecules via a variety of mechanisms. These largely include non-covalent and, in some cases, covalent interactions as well. In addition, the energetic consequences of such interactions are also important. There are several analytical strategies available to understand such interactions between therapeutic agent and biological receptor. Spectroscopic techniques such as UV, Fluorescence and CD are useful to estimate the strength of interactions. The interpretation of binding interactions can be carried out using appropriate mathematical models such as Scatchard plots or Stern-Volmer quenching constants in case of fluorescence quenching experiments. Some of these methods have been utilized to provide an estimate of the overall binding along with stoichiometric assessment of drug-receptor complex. Besides, computational approaches such as Docking, MD and QM-MM calculations have also been applied to study effectively the structural aspects of these complexes. Computational tools have provided structural information in terms of position and orientation of Anticancer agents in the receptor pockets along with their binding free energy values.

Bio-Data:

Research interests of Dr. Neelima Gupta vary from low coordinated phosphorus chemistry, synthetic heterocyclic chemistry to computational chemistry assisted study of reaction mechanism and drug-biomolecule interactions. She has worked as Postdoctoral Fellow at the EMA University, Germany, prior to joining the University of Rajasthan as Faculty. Presently, she also holds position of Joint Director at Centre for Converging Technologies at University of Rajasthan. She started her research in computational chemistry under DST's fast-track project for Young scientists and later was also a visiting scientist to the Computational Chemistry Group in Phillips University of Marburg under Indo-German cooperation program. Dr. Gupta has completed several research projects and has supervised 12 Ph.D. students and has more than 75 Research Publications in International Journals of Repute. She has authored chapters in International Reference Series - Science of Synthesis (Thieme Chemistry), Topics in Heterocyclic Chemistry (Springer-Verlag) and Methods in Pharmacology and Toxicology (Springer-Verlag). Dr. Gupta has received the "Distinguished Women Scientist Award–2019" from the Indian Society of Chemists and Biologists. She was Awarded for Excellence in Research among Top Researchers of the University of Rajasthan in 2009. As one of the founding Conveners of the CRSI-Rajasthan Chapter, she is actively engaged in Chemistry popularization program and is also Secretary in Chemical Research Society of India's present Governing Council. She has organized several National and International Conferences and delivered more than fifty Invited Talks in National and International Conferences, Symposiums, Workshops in India and abroad.

Novel Practicing Catalysts for Extreme Polyethylenes

Wen-Hua Sun, Yanping Ma and Wenhong Yang
Institute of Chemistry, Chinese Academy of Sciences, Beijing 100190, China.
Email: whsun@iccas.ac.cn Website: http://whsun.iccas.ac.cn

Over past two decades, late transition metal complexes as precatalysts has been extensively studied for ethylene polymerization and oligomerization besides titanium,[1] chromium[2] and vanadium catalysts[3]. These types of homogeneous catalysts, pioneered by Brookhart[4,5a] and Gibson,[5b] have been attracted much attentions by the scientists from academic and industrial views across the world.[6] Indeed, various important developments have been made in not only bench-top researches but also industrial scale-up processes. In addition to conventional polyethylene materials, new types of polyolefinic materials are accessible displaying unique properties and microstructures: highly linear polyethylenes using iron (and cobalt) precatalysts[7,8] as well as highly branched polyethylenes using nickel.[8,9] In fact, simple modifications or variations of the chelating ligands can have profound effects on performance which can manifest itself in higher efficiency and increased thermo-stability. Moreover, these technologies are scalable with linear and highly branched polyethylenes now produced on the pilot plant level.

Bio-Data:

Prof. Dr. Wen-Hua Sun heads a group of organometallic chemistry and catalysis at the Institute of Chemistry, Chinese Academy of Sciences since 1999, has also been a chair professor in the University of Chinese Academy of Sciences from 2014. He was selected as Fellow of Royal Society of Chemistry and member of European Academy of Sciences. His contributions have had international impacts across the areas of polymerization catalysts for conversional alpha-olefins and polyolefins, biodegradable polymers and bio-massive process as well as their intermediates and reaction mechanism. His major subjects includespolyolefin oriented organometallics and pilot process of ethylene oligo/poly-merization as well as industrial processes.

Multiple Facets of Physical Gels and Soft Nanocomposites

Santanu Bhattacharya
Director, Indian Association for the Cultivation of Science
director@iacs.res.in
and
Indian Institute of Science,
Bangalore 560 012, India

Physical gels unlike their polymeric counterparts are interesting materials owing to their widespread existence and amenability to tailoring into numerous applications. Much of these are achieved through self-assembly and intelligent applications of Supramolecular Chemistry. In this talk, I shall present various applications that can be achieved using such strategies from first principles.

Bio-Data:

Professor Santanu Bhattacharya is the Director of Indian Association for the Cultivation of Science and is an elected fellow of the Indian National Science Academy, The World Academy of Sciences and the Indian Academy of Sciences. His work has often led to conversations across disciplines in order to identify new areas of research and innovation. Some of the modern methods of therapeutics that he works on are at the cross sections of cell biology, chemistry and materials science. He spearheaded the design of unnatural and natural lipids and peptides, peptide assemblies, which contributed to understanding in membrane biophysics, gene delivery etc. He work also extends to soft gels and polymeric materials, nanocomposites, colloid surfaces; biomaterials, Langmuir films, covalent-organic frameworks and sensor design. He has published over 300 papers and reviews in peer-reviewed journals (h-index > 69). He has been a Professor (2001-), and was the Chairman (2012-15) of Organic Chemistry, at the Indian Institute of Science, Bangalore. Dr. Bhattacharya received his PhD from the Rutgers University, NJ, New Brunswick (1988), and had post-doctoral stint under the tutelage of Professor Har Gobind Khorana, Nobel laureate at the Massachusetts Institute of Technology - the theme of his studies being signal transduction of membrane proteins. He is a recipient of several honors and awards including the S. S. Bhatnagar Prize, Swarnajayanti Fellowship, and National Bioscience Award for Career Development award (DBT), G D. Birla Prize Ranbaxy Prize, Sastra-CNR Rao Award and the TWAS Prize in Chemistry.

Novel Strategies in Electrochemistry: Simultaneous Water Splitting and CO_2 conversion in One Electrochemical Reaction

Prof. Deepa Khushalani
Tata Institute of Fundamental Research
khushalani@tifr.res.in

It is well accepted now that concurrent to the increase in population, India's rapid economic growth has forced us to recognize the challenge of providing advanced materials to address many problems currently plaguing our nation. Among them, dealing with energy supply, pollution and improved medical care are some of the issues that are being addressed in our lab. We work on the selective processing of inorganic structures with features on the nanometer scale. These materials are known to possess interesting and useful optical, electronic and/or magnetic properties that can subsequently be exploited in a wide variety of applications ranging from novel forms of catalysis to solar energy conversion. The choice of application is contingent on not only the chemical composition of the material but also on the overall morphology, and even more precisely on the accessible surface area. As such, the emphasis in our lab has been to use synthetic inorganic chemistry as a tool to form intricate structures that are then exploited in applications predominantly associated with solar energy capture and conversion. Presented in this talk will be novel electro- catalysts for combining pollution remediation AND water splitting electrochemical reactions. This unique approach will be detailed as to how it can yield value added (and industrially applicable) chemicals and also tackle pollution remediation in onestep.

Bio-Data:

Dr. D. Khushalani is Professor in Materials Chemistry, Department of Chemical Sciences, Tata Institute of Fundamental Research (TIFR), Mumbai . She is the winner of Bronze Medal in Chemistry 2018, DST (Nanomission) Young Career Award in Nanoscience and Technology2016, Fellow of Royal Society of Chemistry (FRSC), Chair of RSC West India Section, Editorial Board Member of Scientific Reports (Nature Publishing Group), member of Indian Academy of Sciences – Women in Science Panel, member of Royal Society of Chemistry, UK – Inclusion and Diversity Committee.

Her area of expertise involves synthesis, characterization and application of a variety of inorganic structures such that (1) the morphology, phase, and size are carefully manipulated so that there is precise control over homogeneity and compositional purity, (2) the ensuing materials are applied in areas exploiting alternate sources of clean energy involving photovolatics and energy storage devices.

Density Matrix Renormalization Group Studies on Polyaromatic Hydrocarbons – Effect of Spin Frustration and Topology

Debashree Ghosh
School of Chemical Sciences, Indian Association for the Cultivation of Science
pcdg@iacs.res.in

Polyaromatic hydrocarbons (PAHs) such as acenes have long been studied due to its interesting optical properties and low singlet triplet gaps. Earlier studies[1,2] have already noticed that use of complete valence active space is imperative to the understanding of its qualitative and quantitative properties. Since complete active space based methods cannot be applied to such large active spaces, we have used density matrix renormalization group (DMRG)[3] based approaches. Further small modification to the PAH topology shows interesting new phases of behaviour in its optical gaps. We have understood the effect of these effects based on spin frustration due to the presence of odd membered rings. In this talk, I will discuss these observations from molecular and model Hamiltonian perspectives.[4]

1. The radical character of the acenes: A density matrix renormalization group study, J. Hachmann, J.J. Dorando, M. Aviles, G.K.-L. Chan, *J. Chem. Phys.*, **127(13)**, 134309 (2007).
2. Singlet triplet gaps in polyacenes: a delicate balance between static and dynamic correlations investigated by spin flip methods, C.U. Ibeji, D. Ghosh, *Phys. Chem. Chem. Phys.*, **17(15)**, 9849 (2016).
3. Orbital Optimization in the density matrix renormalization group, with applications to polyenes and beta carotene, D. Ghosh, J. Hachmann, T. Yanai, G. K.-L. Chan, *J. Chem. Phys.*, **128(14)**, 144117 (2008).
4. In the quest for a stable triplet state in small polyaromatic hydrocarbons: an in silico tool for rational design and prediction, M. Rano, S.K. Ghosh, D. Ghosh, *Chemical Science*, **10**, 9270 (2019).

Bio-data :

Debashree Ghosh is an Associate Professor at the Indian Association for the Cultivation of Science. She did her PhD in theoretical chemistry from Cornell University and did a stint of postdoctoral research at University of Southern California before joining her independent research position in India. She is working towards elucidating the mysteries of light matter interaction and uses theoretical approaches to achieve this goal.

The Advantages of 'Broad-band Excitation' and 'Broad-band Emission' Based Analysis

Ashok Kumar Mishra
Department of Chemistry, Indian Institute of Technology Madras, Chennai 600036, India.
mishra@iitm.ac.in

Generally for complete analysis of multi-fluorophoric systems (like petroleum and vegetable oils, dissolved organic matter in water, urine, blood, polycyclic aromatic hydrocarbons in various media, petrochemicals etc.), conventional emission spectra with single wavelength excitation are not suitable[1]. Technique like Excitation-Emission Matrix (EEM) imposes certain limitations on the rapidity of data acquisition.

'Broad-band excitation' and 'broad-band emission' measurement method have been reported in old literature[1], but they have never been popular due to their poor resolving power and analytical limitations. Our research group has introduced some novel unconventional analytical concepts involving these techniques that have made analytical measurements fairly robust.

Prakash and Mishra have used white light excitation fluorescence (WLEF) measurements using an in-house built fiber-optic spectrofluorometer for analysis of multi-fluorophoric systems. Unlike single excitation and emission based fluorescence measurements, WLEF helped in capturing total fluorescence response of the sample over entire UV and Visible region in a single scan. Prakash and Mishra have successfully demonstrated the utility of WLEF technique for the analysis of pharmaceuticals in bio-fluids[2], dip-probe estimation of fluorophores [3] and estimation of composition of petroleum fuel-biofuel mixtures [4]

Panigrahi and Mishra have utilized WLEF concept in a commercial table-top spectrofluorometer for analysis of oils, urine and optical brighteners [5]; the authors have also demonstrated the utility of broad-band UV excitation in fiber-optic spectrofluorometer for analysis of fluorescent dissolved organic matter using a reflective walled sample compartment[6,7].

A time-resolved fluorescence data acquisition technique termed as "Total Emission Time Resolved Decay" (TETRD) has been proposed; TETRD is recorded by using zero-order diffraction of emission grating in TCSPC instrument[8]. It is effective in collecting all the decay related information expediently. With the use of an appropriate data analysis tool (like Stretched exponential function fitting and global analysis), the multi-component decay profiles could be resolved conveniently.

Bio-Data:

Professor Ashok Kumar Mishra completed his Master of Science from University of Delhi in 1980 and received PhD from IIT Kanpur in 1985. After a stint in Sambalpur University as a faculty member, and in Gunma University (Japan) as a Monbusho fellow, he joined IIT Madras in 1992. He was a JSPS Visiting Scientist in Gunma University, Japan during 2002-2003. Currently he is working as Professor in the Department of Chemistry, IIT Madras. He also handles the responsibility of Dean Academic Research at IIT Madras.

Prof Mishra is a Fellow of the 'National Academy of Sciences, India'. Awards received by him include 'CRSI Bronze Medal' from the Chemical Research Society of India, 'Acharya P C Ray Memorial Award' from Indian Chemical Society and 'Prof W U Malik Memorial Award' from The Council of Chemists.

Prof Mishra works in the general area of Physical Photochemistry and Fluorescence Spectroscopy. He has an active research group. So far he has guided 27 PhDs, many M.Sc. students, and published about 210 research papers, reviews and monographs.

Luminescent Metal Nanoclusters: Spectroscopic Signatures and Applications

Saptarshi Mukherjee
Professor, Department of Chemistry
IISER Bhopal
Email: saptarshi@iiserb.ac.in

Metal nanoclusters (NCs) have attracted a lot of research attention of late, primarily due to their advantage of exhibiting size dependent optical properties, better water solubility, biocompatibility, and low toxicity. They are now considered as the next generation fluorophores. In my talk I shall discuss some of the spectroscopic signatures of metal NCs (with emphasis on Cu NCs). Also, how these NCs can serve as a nanothermometer, discriminate between single base pair mis-matches in DNA, specific metal ion sensors, nuclear membrane markers, bio-sensors etc. will be discussed.

5. S. Ghosh, U. Anand and S. Mukherjee, *J. Phys. Chem. C* (119)**2015**, 10776.

Bio-Data:

Dr. Saptarshi Mukherjee did his BSc and MSc from Jadavpur University and completed his PhD from IACS Kolkata in 2006 under the supervision of Professor Kankan Bhattacharyya. During his PhD tenure, he used time-resolved spectroscopy to study organized assemblies. He moved to Bowling Green State University, Ohio, USA to carry out his post-doctoral research with Professor H. Peter Lu on single molecule enzymology. He returned to India and joined the Department of Chemistry, IISER Bhopal in December 2008 as an Assistant Professor. He became a full Professor in January 2018.

He is also the Deputy Director of IISER Bhopal since March 2018. His research interests include ultrafast and single molecule spectroscopy of luminescent metal nanoclusters, biological assemblies and surface chemistry. He is the recipient of the INSA Young Scientists Medal, founding core member of INYAS, recipient of CRSI Young Scientist Medal and CRSI Bronze Medal. Professor Mukherjee is also the Senior Editor of the journal, Chemical Physics Impact, published by Elsevier.

Molecular Approaches to Control Coherence in Singlet Fission

Satish Patil
Solid State and Structural Chemistry Unit
Indian Institute of Science, Bangalore
E-mail: spatil@iisc.ac.in

Emerging light harvesting materials such organic semiconductors have proved successful in terms of costs but encountered a limit for device efficiency. The fundamental limits based on the Shockley-Queisser detailed-balance model provides a basis for identifying the key limiting factors, related to efficient light management and charge carrier collection. It has been shown multiexciton generation through singlet fission has the potential of exceeding Shockley–Queisser limit in photovoltaic devices. However, only very few materials suitable for singlet fission are available at present and the mechanism of inter- and intra-molecular singlet fission are not fully understood. Detailed knowledge regarding the processes is crucial for developing new materials. In this talk, I will present the molecular design and synthesis strategies to meet the exchange energy and morphology criteria for molecules to undergo singlet fission.

Dr. Patil is Professor in Indian Institute of Science, Bengaluru. He obtained his Ph.D. in Polymer Chemistry), Bergische University of Wuppertal, Germany (2004). He is the recipient of several prestigious awards and recognitions like Swarnajayanti fellowship (2013-2014), Young Affiliates of the World Academy of Sciences (2013), INSA Young Scientist Award (2009), Young Associate of the Indian Academy of Science, Bangalore (2009-2012), Chemical Research Society and Materials Research Society of India Bronze Medal (2012), Professor Kaushal Kishore Memorial Award of the Society of Polymer Science, India (2014), A V Ramarao Research Foundation Young Scientist Award (2012), Microsoft Research (MSR) India Outstanding Young Faculty Award (2009). He is also an Editorial Board Member of iScience, Associate Editor of Resonance - Journal of Science Education and Editorial Board Member of ACS Chemical Health and Safety.

Solubilization Behavior of Hydrophobic Drugs in Pure and Mixed Micelles of Pluronic Triblock Copolymers

Rakesh Kumar Mahajan
Department of Chemistry, UGC-centre for Advanced Studies-I, Guru Nanak Dev University, Amritsar 143005, India.
rakesh_chem@yahoo.com

Solubilization study of hydrophobic drugs into pluronic co-polymeric micelles has gained great interest because these solubilized formulations have increased solubility, metabolic stability and circulation time. Moreover mixed micelles manifest synergistic properties, such as increased micelle stability and drug loading efficiency, superior to those of the individual micelles. The solubilization of hydrophobic drugs *viz.* Oxcarbazepine (OXC), Lamotrigine (LAM) Clozapine (CLZ) and Quercetin (QCT) have been studied in pluronics and pluronics-mixed micelles with other amphiphiles such as surface active ionic liquids (SAILs) and Bile salts, Sodium deoxycholate (SDC) employing state of art techniques. UV-visible spectroscopy has been exploited to determine the solubilization capacity of the investigated micellar systems in terms of drug loading efficiency, average number of drug molecules solubilized per micelles (n_s), partition coefficient (P) and standard free energy of solubilization (ΔG). The locus of hydrophobic drugs in different pluronic and pluronic mixed micelles has been adjudged by ^{1}H NMR, Micropolarity, Small angle neutron scattering (SANS) and isothermal titration calorimetry (ITC) measurements. Dynamic light scattering (DLS) have been employed to determine the hydrodynamic diameter (D_h) of loaded and unloaded micelles. The results of the present studies will discuss in detail at the conference.

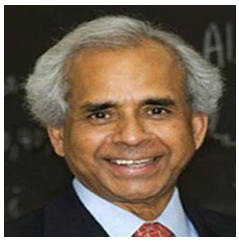
Bio-Data:

Prof. (Dr.) Rakesh Kumar Mahajan has joined back as Professor (Re-employed) on June 2019 at Chemistry Department of Guru Nanak Dev University Amritsar after serving as the Vice-Chancellor of DAV University, Jalandhar from December 2017 to June 2019. Prior to joining DAV University, he has held various prestigious assignments at Guru Nanak Dev University (GNDU), Amritsar. During his tenure as Professor of Chemistry at GND University, he has held several additional posts being the Head of Chemistry Department, Dean in the Faculty of Sciences, Professor In-Charge (Examinations) in the office of Controller of Examinations, Dean, Colleges Development Council and Coordinator in University-Industry Linkage Programme.

His areas of research specialization include Chemical Sensors, Colloids and Interfaces, Environmental Chemistry and Material Science. To his credit lies the publication of more than 171 research papers in several journals of international repute. In addition, he serves as a referee in a number of renowned journals by Elsevier, American Chemical Society (ACS), Springer, Royal Society of Chemistry (RSC), Wiley, Taylor & Francis and many other publishing houses. He is a reviewer of various research schemes submitted to UGC, CSIR, DST and Ministry of Forest and Environment, New Delhi. He is also a subject expert member of many committees of various universities and national organizations.

In lieu of his contributions, Indian Chemical Society bestowed him with P.K. Bose Memorial Award-2009, at Annual Convention of Chemists, Raipur in December 2010. Awarded CRSI Bronze Medal by Chemical Research Society of India at the 16th CRSI National Symposium in Chemistry held at IIT Bombay during Feb. 7-9, 2014. He was elected fellow in the year 2015 of The National Academy Of Sciences, INDIA (F.N.A.Sc.) and in the year 2019 of Punjab Academy Of Sciences, (F.P.A.S.)

Chemistry Beyond Conventional Wisdom*



Puru Jena
Physics Department, Virginia Commonwealth University, Richmond, VA 23284, USA
pjena@vcu.edu

One of Chemistry's biggest contribution to materials science is the Mendeleev's periodic table of elements. Created in 1869 before the discovery of the electron and the knowledge of quantum mechanics, the periodic table explains the chemistry of elements in terms of their valence electrons. Zinc, for example, is divalent. With an outer electron configuration of $4s^2$, two Zn atoms bind weakly, but bulk Zn is metallic. The outer electron configuration of noble gas atoms, on the other hand, is ns^2np^6. Because of the closed shells (the octet shell closure), noble gas atoms are chemically inert. Zn being trivalent and noble gas atoms forming chemical bonds at room temperature should be against conventional wisdom. In this talk I will discuss ways in which zinc can assume a +III oxidation state and noble gas atoms, including argon, can form a covalent bond at room temperature. These unexpected features are made possible by the use of highly electronegative clusters that exist in multiply charged states in the gas phase. In particular, $BeB_{23}(CN)_{22}$ cluster, stable as a tetra-anion in the gas phase, can make Zn to assume +III oxidation state, while $B_{12}(CN)_{11}^-$ cluster can bind argon with a binding energy of 0.6 eV. The results are based on density functional theory with dispersion correction and predictive capability. The rational design of clusters with electron affinities far exceeding those of halogen atoms and their ability to promote chemical reactions once thought impossible can usher a new era in chemistry.

*Work performed in collaboration with Dr. Hong Fang and supported by the Department of Energy

Bio-Data:

Dr. Puru Jena is Distinguished Professor of Physics at Virginia Commonwealth University. He served as Program Director at the Materials Science Division of the National Science Foundation during 1986-87 and as Jefferson Science Fellow and Senior Science Advisor at the US Department of State during 2007-08. Dr. Jena's research covers a wide range of topics in nano-structured materials, condensed matter Physics, and materials Science. He is the author of more than 630 papers including 13 edited books. His Google citations and H index are 31,000 and 87, respectively. He has given over 500 invited talks in 32 countries, including over 250 invited talks at international conferences and has organized 60 international conferences. Some of Dr. Jena's many honors include Fellow of the American Physical Society; Outstanding Scientist of Virginia; Presidential Medallion, University Award of Excellence, and Outstanding Scholar of Virginia Commonwealth University; and Outstanding Faculty Award from the State Council of Higher Education of Virginia. He has served as a member of numerous scientific panels at the National Academy of Sciences. National Science Foundation, Department of Energy, Army Research Office, Virginia Governor's task force on green energy technologies and co-chair of the Presidential Commission on bilateral scientific collaboration between USA and Russia.

Cucurbituril-based Functional Supramolecular Assemblies: Prospective Applications

Jyotirmayee Mohanty
Radiation & Photochemistry Division Bhabha Atomic Research Centre
Mumbai-400094, INDIA;
jyotim@barc.gov.in

Of late, there is an upsurge in the research of supramolecular assemblies of organic guests using various macrocyclic receptors and biomolecules as they provide a unique way to control the sophisticated nanoarchitectures to create supramolecular functional assemblies. Among many different strategies for making such functional assemblies, non-covalent host-guest interactions have recently received large attentions in a variety of scientific fields due to their unique assembly characteristics and functional performances. Macrocyclic hosts such as cucurbiturils, calixarenes and cyclodextrin derivatives have gained immense research interest because of their ability to host, in a highly selective manner, certain types of guest molecules such as metal cations, protonated alkyl and aryl amines, cationic dyes, amino acids and drugs through ion-dipole interaction and hydrophobic interactions. The presentation will cover some of the recent work on the spectacular molecular properties of macrocyclic host-assisted functional assemblies of few organic dyes/drugs having technological and biological importance and their projected applications toward the aqueous dye laser, fluorescent sensors, ^{99m}Tc generator bed, amyloid fibril inhibitors, antibacterial agents and controlled drug delivery.

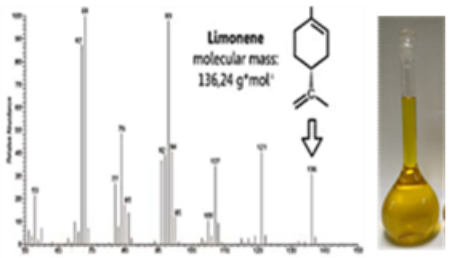
Extraction of Essential Oils from the Peels of Pomelo Fruit and Their Dispersion in aqueous based media with or without a Surfactant for Targeted Applications

Homendra Naorem
Department of Chemistry
Manipur University, Canchipur, Imphal, Manipur
naorem.homendra@gmail.com

Fruit peels which are generally disposed haphazardly adding to environmental problems in the country in general and the state of Manipur in particular are rich sources for essential oils. We have developed a simple mechanical method for extraction of essential oils from the peels of Pomelo fruit (Citrus maxima, local name – Nobap)grown abundantly in Manipur. We have also set up a hydro-distillationunit using glassware apparatus in the laboratory for extraction of the essential oils. Both the methods are simple, effective and user friendly.

Pomelo Plant

Pomelo Fruit Peels



GCMS of the essential oil

The preliminary studies showed that the oil extracted by the mechanical method is superior to the one extracted by the hydro-distillation method both in terms of the quantity and the quality.Results from GC-MS, UV-Vis and FT-IR revealed that limonene is the major component of the essential oil constituting about 79% while others likePinene, Myrcene, etc. are present as minor components.The essential oil exhibited the antibacterial activities against both B.subtilis and E.coli. The ternary phase diagram of the oil and water with an organic alcohol or a non-ionic surfactant or their mixtures have been developed with a view to dispersing the oil in aqueous based media. The surfactants studied include TX-100, Tween-20, Tween-40, or Igepal. Among the surfactants studied, Tween-20 was found to be most effective dispersant. Formation of gels in specific regions in the systems containing TX-100, Tween-80, or Igepal was observed which can be de-gelled by addition of an organic alcohol. The details will be discussed during the talk.

Bio-Data:

Dr. Homendra Naorem is Professor of Physical Chemistry at Manupur University. His research area of interest lies in Self-aggregating systems, surfactants, dyes, polymer, dye-polymer-surfactant interactions, entrapment of dyes in soft gel network materials, development of dye sensitized solar cells, etc. He has published more than 50 papers. He has received many awards like DST-MASTECH Young Scientist at PSU, IACS, Kolkata(1997), JC-Bose Visiting Professor at SPS, JNU, New Delhi(2009), Honour Medal from DAV Women's College, Amritsar(2011), Centenary Award Medal Talk from Shanxi University, Shanxi, China(2012), BN Gosh Memorial Award and Medal (2012) by the Indian ChemicalSociety, Appreciation Award from Chemistry Department (2014) NEHU, Shillong. Professor Naorem is a member of several professional bodies like CRSI for the terms 2011-14 and2014-17, elected executive Member Indian Soc for Surfactant Sc& Technology (ISSST), Indian Thermodynamics Society(ITS), Secretary General, NE Chapter of ISSST, Life member Indian Chem Soc, Polymer Soc India. He has undertaken more than 9 major projects and produced 8 completed PhDs.

Allosteric Regulation of Molecular Tunnels

Ruchi Anand
Department of Chemistry, Indian Institute of Technology Bombay, Mumbai-400076, India
ruchi@chem.iitb.ac.in

Molecular tunnels in multifunctional enzyme systems allow the passage of labile intermediates. In most cases this process is governed via allosteric cues that aid in transfer of signals. Here, we investigate the mechanism of ammonia passage in bi-functional enzyme formylglycinamidine (FGAM) synthetase that catalyzes a key step in the essential purine biosynthetic pathway which help synthesis bases that act as building blocks for DNA and RNA. Ammonia is produced in the glutaminase domain and it traverses to the FGAM synthetase domain, via a ~ 25 Å long transient hydrophobic tunnel converting formylglycinamideribonucleotide (FGAR) to formylglycinamidineribonucleotide (FGAM). The enzyme has an extra 200 amino acid domain at the N terminus which has been shown to be essential for function but possesses no active site residues[1]. The exact allosteric switch as well as the path followed by ammonia had remained elusive for decades. Some insights into the pathway emerged via carrying out RISM calculations[2,3]. Here, by a combination of X-ray crystallography and biochemical studies, we unravel the origin of the allosteric switch. Combinatorial molecular dynamics studies, validated by experiment, reveal that the partially unfolded state of a catalytic loop that resides near the FGAM synthetase active site is key towards transmitting the signal via the bridging N-terminal domain. This facilitates the restructuring of the glutaminase site to its active form along with the concomitant formation of the ammonia tunnel. Furthermore, a dual gating mechanism controls the release of ammonia via a timely swinging motion of the two extreme gates. This study asserts that substrate channelling is modulated by allosteric hot-spots that alter the protein energy landscape thereby, allowing it to adopt transient conformations, paramount for function.

Bio-Data:

Dr. Ruchi Anand completed her PhD in 2004 from the Department of Chemistry and Chemical Biology at Cornell University, USA. After conducting postdoctoral research at Sloan Kettering and the University of Pennsylvania she joined IIT-Bombay in 2008 as an Assistant Professor. Her laboratory employs a combination of X-ray Crystallography, Cryo-EM, biochemical and biophysical tools to understand molecular mechanisms with implications to human health. Her current research interests follow a multipronged approach where she has contributed to two major areas, antimicrobial resistance and biosensors development. Towards the first goal of combating drug resistance she focuses both on unearthing enzyme systems that can serve as new therapeutic targets as well as is involved in understanding the origins of antibiotic resistance itself. Her recent work with bacterial transcription factors has paved the way to structure-guided development of biosensors for aromatic pollutants. Since 2016, she has been serving on the Editorial Advisory board for ACS Sensors. She was the recipient of the National Academy of Sciences Fellowship (FNASc) in 2019 and also won the National Women Bio-scientist Award, Department of Biotechnology, in 2018 and was awarded the CRSI bronze medal for 2020." She was also awarded the DBT-Wellcome Trust Alliance Senior Fellowship earlier this year.

Plasmonic Platforms for SERS: From Fundamentals to Translational Research

K. George Thomas
SchoolofChemistry, Indian Institute of Science Educationand Research
Thiruvananthapuram (IISERTVM), Vithura, Thiruvananthapuram695551, India
E-mail: kgt@iisertvm.ac.in

Excitation of surfaceplasmons in metal nanoparticles is associated with collective oscillation of conduction electrons, leading to the generation of a large electric field on its surface which decays with distance.[1,2] Generation of such rather large electric fields around metal particles resulted in numerous interesting advances in the area of spectroscopy; for example, surface-enhanced Raman scattering (SERS).[3] Precise assembly of plasmonic materials of desired size and shape allows further modulation of their optical and field effects.Assembled plasmonic nanostructures create regions of enhanced electric fields at the nanogaps (hot spots) due to surface plasmon coupling, which are significantly higher compared to the monomeric nanostructures.[4-6] Owing to the enhanced electric fields, analyte molecules placed at the nanogaps of assembled nanostructures showed considerably large enhancement in the spectroscopic signals. We have investigated the effect of the field on SERS at the vicinity of plasmonic nanoparticles and hot spots and further translated these concepts for the design of plasmonic platforms, which can identify molecules of importance in health, environment and safety.[7-10] Taking these ideas forward,we have developed of a customized Raman spectroscopy device (with the technical support of Prof Chandrabhas Narayana of JNCASR, Bangalore) interfaced with an in-house developed plasmonic platform based on various core-shell plasmonic nanostructures and data processing software for rapid detection of pesticide/insecticide residues from vegetables and fruits (supported by IMPRINT Project). These aspects will be presented.

Bio-Data:

Dr. Kakkudiyil George Thomas (born 1961) is an Indian photochemist, nanomaterial scientist and a professor at the Indian Institute of Science Education and Research, Thiruvananthapuram. He is known for his studies on photoresponsive nanomaterials and is an elected fellow of the Indian National Science Academy and the Indian Academy of Sciences The Council of Scientific and Industrial Research, the apex agency of the Government of India for scientific research, awarded him the Shanti Swarup Bhatnagar Prize for Science and Technology, one of the highest Indian science awards, in 2006, for his contributions to chemical sciences. K. George Thomas, born on 13 May 1961 in the south Indian state of Kerala, did his early schooling at his home state before joining Savitribai Phule Pune University from where he completed his master's course (MSc) in chemistry in 1983. He returned to Kerala for his doctoral studies under the guidance of K. Saramma and secured a PhD from the University of Kerala in 1989. His post-doctoral studies were at the Photosciences and Photonics Group of Manapurathu Verghese George at National Institute for Interdisciplinary Science and Technology (NIIST) as a research associate and after completion of the studies in 1994, he continued at NIIST to start his career as a scientist. Subsequently, he joined Indian Institute of Science Education and Research, Thiruvananthapuram and serves the institution as a professor while continuing his researches at NIIST. He has also had various stints at the University of Notre Dame in 1999, 2003, 2004 and 2005 as a visiting faculty and is an honorary faculty fellow at Jawaharlal Nehru Centre for Advanced Scientific Research.

Quantum Dots to Perovskites. How Semiconductor Nanostructures are Shaping Light Energy Conversion

Prashant V. Kamat

Radiation Laboratory, Department of Chemistry & Biochemistry, University of Notre Dame, Notre Dame, IN 46556

E-mail: pkamat@n.edu*

Semiconductor nanostructures with tunable photoresponse can capture the visible and near IR photons quite effectively. By controlling the size and composition one can tune the photoresponse of semiconductor nanostructures in the entire visible region. Assembling these nanostructure assemblies on electrode surfaces in a controlled fashion is an attractive approach for designing next generation solar cells.[1,2] The key advantage of semiconductor nanostructures lies in designing thin film solar cells with low temperature processing. These advantages significantly decrease the energy payback time since less energy is consumed (and hence a lower carbon footprint) during their manufacture.

The early studies which focused on the synthesis of semiconductor quantum dots and elucidation of charge carrier dynamics have led to the evolution of high efficiency metal halide perovskite solar cells.[3,4] In the present talk light induced charge carrier generation and transport across interfaces which are important in the operation of solar cells will be discussed. Photoinduced segregation in mixed halide perovskite has a direct influence on decreasing the solar cell efficiency as segregated I-rich domains serve as charge recombination centers.[5] Recent developments in utilizing semiconductor quantum dots in light energy conversion will be discussed.

Bioorganometallic Chemistry: Synthetic Strategies and Biomedical Applications for Metal-Peptide Bioconjugates

Nils Metzler-Nolte*
Ruhr University Bochum, Bochum, Germany
nils.metzler-nolte@rub.de

Our group uses the unique spectroscopic and chemical properties of organometallic complexes in metal-peptide conjugates for biomedical applications. The experimental challenge is to identify air- and water stable organometallic compounds with the desired properties, and to devise methods for the mild, biocompatible synthesis of bioconjugates with these metal complexes. Similarly, biomedical properties of peptides have been tailored by their conjugation to organometallic moieties.

This presentation will highlight various synthetic strategies to obtain bioactive metal-peptide bioconjugates that have been developed in our group, and will present some exemplary biomedical applications of such metal-peptide conjugates. I will show how the versatile reactivity of metal complexes can be matched with peptide chemistry and purification techniques. Potent novel anticancer agents based on a number of different metals such as Fe, Ru, Re, and Au were developed, characterized and tested for their antiproliferative activity against a range of different cancer cells. Here, I will also present results on organometallic derivatives of neuropeptides which bind to the opiod receptors, which in turn belong to the now-famous class of G-protein coupled receptors (GPCRs). The solution structures by NMR of a Cp*Rh complex covalently linked to GPCR-binding peptides like somatostatin and enkephalin was reported by us, and the binding to the opiod receptors was investigated by NMR and molecular modelling. More recently, our group prepared the first metal derivatives of the peptide dermorphin, which unlike enkephalin has excellent specificity for the μ-opiod receptor. A hitherto unknown binding mode was discovered, and the physiological consequences were investigated experimentally, including *in vivo* experiments in mice. Finally, utilizing a novel uncatalyzed, chemoselective cycloaddition reaction for bioconjugation we could link Au complexes to peptides with high yield and purity. Biochemical and cell biology results are presented that support enzyme inhibition as the mode of action. Interestingly, these Au-peptide bioconjugates show no cross-resistance to the well-established Pt antitumor drugs.

Bio-Data:

Prof. Dr. Nils Metzler-Nolte is the Professor and Chair of Inorganic Chemistry I, Ruhr-University Bochum since 2006. He was the Dean of the Ruhr-University Research School for Graduate Studies during 2009 – 2012 and the Vice-President for Early Career Researchers and International Affairs of Ruhr University Bochum during 2010 – 2012. He has received several awards and honors like the Karl-Ziegler-Fellowship of the German Chemical Society in 2001, Award for Innovative Teaching, Ruhr University, 2010, Julius van Haast Award of the Royal Society of New Zealand, 2015, Elsevier Award for Outstanding Achievements in Bioorganometallic Chemistry, 2019. He was also a Visiting Professor at the Universities of Milan (Italy), Stellenbosch (South Africa), Paris 6 (France), Auckland (NZ) and Fellow of the Royal Society of Chemistry, 2016. He was the Chairman of Third German Ferrocene Colloquium, Heidelberg, 2005 and the fifth International Symposium on Bioorganometallic Chemistry (ISBOMC'10), Bochum, 2010, Chair of the 2016 Gordon Conference "Metals in Medicine" (with K. Franz, Duke Univ., NC), Speaker of DFG Research Unit (Forschergruppe) FOR 630, 2006-2013 and Councillor of the Society of Biological Inorganic Chemistry (SBIC) 2012 – 2015. He acted as the Guest Editor for Thematic Issue of Chemical Reviews "Metals in Medicine", 2019; Associate Editor for Bioinorganic Chemistry Dalton Transactions, 2013 – 2019 and is now designated as the Editor-in-Chief for Journal of Biological Inorganic Chemistry (JBIC). He has more than 200 papers in international peer reviewed journals, 20 Reviews and Highlight articles (with peer-review), 8 book chapters, 1 book, 2 edited books. 2 Patents and 9 journal covers. He has received more than 9600 citations, average 45 citations per paper with h-Index = 50 (as in Sept 2019).

Metal-organic frameworks: a propitious way out for the problem of hydrogen storage

Manisha Jadon[1,2], Tapan Bera[2],*and Arunachalam Ramanan[1]*
[1]Department of Chemistry, Indian Institute of Technology Delhi, India
[2]Indian Oil Corporation Limited, R&D Centre, Faridabad-121007, India
ramanan57@gmail.com

The escalating threat of global warming poses a serious concern regarding global climate change, at an alarming rate, as well as the rising demand of energy worldwide with population growth necessitates the exploration of alternate energy sources. Hydrogen, in this context, is a potential alternative to fulfill these requirements, but it presents several other problems associated with its production, delivery and storage. In this context, porous metal-organic frameworks (MOFs), with high surface area, chemically tunable structures, have been considered as a potential hydrogen storage material. However, weak interaction of H_2 with MOFs requires cryogenic temperature for significant uptake. In this talk, we will highlight the key challenges faced and the possible solutions in the field of hydrogen storage. The talk will focus on the understanding of the mechanism of hydrogen adsorption in MOFs and strategies to design MOFs with increased hydrogen uptake capacity at room temperature.

Bio-Data:

Dr. Arunachalam Ramanan is Professor in the Department of Chemistry and former Heads of School of Interdisciplinary Research (2016-18) & Department of Chemistry (2012-15) at IIT Delhi. He has a long-standing interest in solid state chemistry and Materials chemistry. Since his graduation, he is fascinated by the diversity in solid-state structures (disorder, intergrowth, isostructures, polymorphism, supramolecular isomerism, amorphous) and the need to manipulate molecular aggregation to control its physico-chemical properties. His recent research interests include utilization of hydrogen bond and metal-ligand oordination to design multiple forms of pharmaceutical solids as well as coordination polymers and MOFs. His laboratory investigates crystallization process with an objective to obtain molecular insights into the phase transformation of aggregating molecules leading to a particular form of the solid.

Applications of nanotechnology in Oil & Gas sector

Dr. Samik Kumar Hait
Indian Oil Corporation Limited, R&D Centre, Faridabad
HAITS@indianoil.in

Applications of nanotechnology in energy sector, especially relating to fuels and lubricants & renewables are being explored world over. Use of nanomaterials instead of conventional additives is perceived to enhance performance at lower treat rate. However, stability of various inorganic and organic nano dispersions in hydrocarbon medium during processing, storage and application is a critical issue. Though many groups and organizations are successful in synthesizing and characterizing nanopowders followed by their initial solubilization or dispersion of such kind of nanoparticles in hydrocarbon/oil medium, severe problems are being encountered in maintaining their long term storage stability in oil matrix especially at low and normal temperatures as well as under accelerated test conditions. This aspect, coupled with the prohibitive cost of procured nanoparticles is acting presently as major deterrents for adopting these nanodispersions on a large scale as effective alternatives for the conventional additives towards oil and gas applications.

IOCL R&D Centre made an initiation in nanotechnology research for development & deployment of nanotechnology interventions in the application of fuels and lubricants. Several nanomaterials and nanodispersions have been synthesized using both top-down and bottoms up approach and explored for desired performance. Some of these nano-products were scaled up controlling the quality of the same. Stability issues of such dispersions were effectively addressed during development. Patent applications were also filed for preparation and evaluation methodologies of such dispersions. Attempt to enhance the performance by application of nanotechnology in alternatative and renewable will also be touched upon.

This topic highlights some of the IOCL developmental work and application results of IndianOil's patented nanodispersion in different products along with associated challenges. A few case studies including field validations of these nanodispersion in respective product formulations will also be presented.

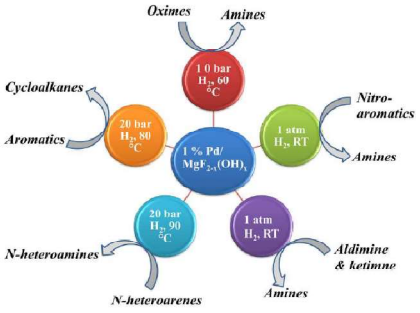
Bio-Data:

Dr. Samit Kr Hait is the Chief Research Manager of IOCL R & D Centre. He has obtained his PhD from Jadavpur University. His area of research interest is Energy, Surface science, material chemistry. He has 30 International publications in the journals of repute, 15 patents, 18 years of experience in energy sector and nanotechnology application and is the recipient of Bangalore Nano Innovation Award, FIPI Innovation of the year-team award

Metal Fluorides as Nonconventional Support for Palladium nano-particle for hydrogenation under ambient conditions

Shubhangi B. Umbarkar
CSIR-National Chemical Laboratory, India,
sb.umbarkar@ncl.res.in

Metal fluorides are emerging as new hi-tech materials in catalysis, ceramics, thin optical films, anti-reflective coatings, hosts for laser devices, and energy storage devices.They are used in different forms such as simple binary, oxy / hydroxyl, complex or doped fluorides, etc. By using or combining different metal cations in the fluoride matrices, it is possible to prepare materials with a wide range of desired properties. Metal fluorides possess the strongest electronegative element, which generates a higher Lewis acidity on the metal center compared to their corresponding oxides and other metal halides. A support plays a vital role in heterogeneous catalysis, hence a large number of supports has been explored for synthesis of efficient catalysts. Support not only helps adsorption and desorption of reactants and products but also has a substantial influence on the electron transfer, adsorption capacity, chemical and electronic structure of the active metal. The metal support interactions in catalysts depend on the characteristics of the support such as surface area, crystal facets, crystal size of the catalysts and acidity/basicity of the support. Palladium has been extensively used as catalyst in many organic transformations which include formation of C–C, C–O, C–N bonds, oxidation, and hydrogenation. Among all reactions, hydrogenation of organic molecules is probably one of the most important chemical reactions for the synthesis of many compounds. Heterogeneous catalytic hydrogenations are significant reactions that find comprehensive industrial application in the production of pharmaceuticals, agrochemicals, fine chemicals, flavors, fragrances and dietary supplements.



We have explored metal fluorides as non conventional support for palladium nano particles as catalysts for various reactions including hydrogenation of various functionalities like C=C, C=N, -NO_2, -C=O, aromatic ring etc. To our surprise Pd supported on MgF_2 has shown very high efficiency for hydrogenation of C=C, C=O, -NO_2 under ambient conditions and hydrogenation of aromatic ring and reductive amination under milder conditions. The high efficiency of the catalyst was attributed to the very strong metal-support interaction due to acidic nature of the support which led to the formation of palladium nano sheets and very high metal dispersion. The catalyst shown very high efficiency for recycle without any Pd leaching and very high efficiency with only 1% Pd loading leading to very high TON &

TOF. The activation of hydrogen was by heterolytic cleavage on the Pd centre. In many cases the Lewis acidic centre of metal fluoride support helped activation of substrate leading to enhanced activity/selectivity.

Bio-Data:

Dr. Shubhangi B. Umbarkar is the Principal Scientist at Catalysis Division, CSIR-National Chemical Laboratory, Pune. She obtained her PhD from IIT Bombay (1996) in Organometallic Chemistry and pursued her Postdoctoral research as DAAD fellow in Karlsruhe Germany (1998). Her research areas are Environmental catalysis, Rare earth based catalytic materials for automotive applications using Indigenous raw materials (IREL), oxidative desulfurisation, Vvalorisation of bio-derived materials like glycerol, lactic acid, lactates, edible & non-edible oils, Ddevelopment of mesoporous solid acid catalysts, in situ FTIR spectroscopic characterisation, organometallic complexes for catalytic oxidations. She has 74 Publications, 15 patents and 20+ scientific and industrial Projects. She has more than 10 co-operational stays at other Universities abroad. She has guided 9 PhD, 5 M.Tech, 3 M. Phil and 7 M.Sc. students.

Sustainable Chemistry – Growth driver of tomorrow

Dr. Ramkumar Dhruva
President, Monomers Division, BASF SE, Belgium
ramkumar.dhruva@basf.com

Chemistry plays an important role in our lives. We eat them, we drink them, we breath them, and we are made of them. Chemicals are present in 95 percent of manufactured goods, from simple everyday items to hi-tech applications.

Global trends - like population growth, continued urbanization and increasing demand for high-quality consumer goods - provide opportunities for growth in the chemical industry. Asian chemical industry is very diversified, and its home market represents the fasted growing region globally. Asia will contribute close to 80% of the growth in chemical production until 2030. China will continue driving global demand and capacity expansion. The Indian chemical industry is valued at ~$165bn and it is expected to grow at a CAGR of ~9% in the next 10 years contributing significantly for the growth of Indian manufacturing sector.

The global chemical industry is on the cusp of transition and is actively engaged in developing technologies and solutions to create a carbon-neutral, resource-efficient and circular society.

Focusing on sustainable development and especially on circularity, our industry will actively contribute to meeting the commitments of the Paris Climate Agreement, the UN Sustainable Development Goals as well as objectives of the just announced European Green Deal. This offers opportunities for new innovations both in products as well as processes.

This presentation will touch upon some selected solutions and technological innovations that help to keep materials (considering the technical, economic feasibility of doing so) through reuse of materials, resource recovery and waste recycling technologies. It also explores the use of alternative & more sustainable feedstock as a building block of tomorrow's chemical value chains.

Long-term success is only possible if we integrate sustainability deeply into our businesses. As chemical companies, we are only successful when our solutions, products and technologies add value to society. Achieving success needs even closer collaboration than before between industry-players, researchers, and policymakers.

Bio-Data:

Dr. Ramkumar Dhruva was born in India in 1968. In 1996 he earned a Ph.D. in Organic Synthesis, Photo & Electro Chemistry from Indian Institute of Technology, Madras. He was a research chemist in Polymer Dispersions Laboratory in BASF AG, Ludwigshafen, Germany when he joined BASF. Later he became the Chief Executive, BASF Coatings (India) Pvt. Ltd, Mumbai India. Then he became the Vice President, and Senior Vice President BASF Coatings Solutions, Asia Pacific, BASF East Asia Regional Headquarters Ltd., Hong Kong / BASF Japan Ltd. Now he is the President, Monomers, BASF Belgium Coordination, Center Comm. V., Waterloo, Belgium.

Cellulose material for adsorptive removal of heavy metals and organics – mechanism

Prof. Sudip Kumar Das
Department of Chemical Engineering, University of Calcutta, India
skdchemengg@caluniv.ac.in, drsudipkdas@gmail.com

Water pollution is an important issue worldwide. Researchers are working on eco-friendly, sustainable development for the remediation of wastewater. The small and medium-sized industries situated in India's rural areas and 3rd World industries produce large quantities of wastewater containing heavy metal and dyes. As they are situated in rural areas, these industries' problem is forced to drain their wastewater into the local water bodies and agricultural field. Thus it may enter into the food chain. In rural areas, no typical effluent treatment facility is available. Researchers have used different agricultural wastes and their by-products as an adsorbent to remove heavy metals and dye from the wastewater stream. Thus the agricultural wastes and their by-products have an advantage of their low-cost and widely available rural areas.

The agricultural waste and its by-products are cellulosic and contain cellulose, hemicellulose, lignin, and a minimal amount of specialty chemicals are the main constituents. Cellulose is a polysaccharide consisting of a linear chain of several hundred to many thousands of β (1-4) linked D-glucose units. Hemicellulose belongs to a group of heterogeneous polysaccharides formed through biosynthetic routes but different from that of cellulose. Mannose is the essential hemicellulose monomer, followed by xylose, glucose, galactose, and arabinose. Some mannose is acetylated at the C2 or C3 positions, with, on average, one substitute group for every three to four hexose units. Lignin is an alkyl-aromatic polymer.

The cellulosic materials contain different functional groups and are responsible for the binding through electrostatic attraction, hydrogen bonding formation, n–π interaction, and π–π interaction. These interactions may not give very high adsorption capacity than the synthetic adsorbents, but very useful for the rural areas in the 3rd World countries. This paper deals with the possible mechanism of binding the heavy metals or organic pollutants present in wastewater with the agricultural waste and its by-products.

Bio-Data:

Dr. Sudip Kumar Das is currently Professor and Former, Head in the Department of Chemical Engineering, University of Calcutta. He has completed his M. Tech. and Ph.D. in Chemical Engineering from the Indian Institute of Technology, Kharagpur and graduated from the University of Calcutta in Chemical Engineering and Chemistry Hons. He is also actively engaged in research related to different fields of Chemical Engineering, like single and multiphase (gas-liquid) flow through pipelines and piping components, multiphase flow through coils, fluidization and inverse fluidization, wastewater treatment technology, heavy metals and organic pollutants removal from wastewater, Process Plant Safety, Computational fluid dynamics, artificial neural networks and machinable glass-ceramics. He has published 1 book, 15 chapters, more than 200 papers in National and International journals and presented a large number of invited lectures in the Conferences. He has been a reviewer for more than 125 National and International journals. He is member of Refrigeration and Air Conditioning Sectional Committee, ME 03, Bureau of Indian Standard, also in professional societies like, Indian Institute of Chemical Engineers (life), Institute of Engineers (Fellow), IEEE, Indian Association for Air Pollution Control (life), Indian

Chemical Society (Fellow), Millennium Institute of Energy and Environment Management (life), International Congress of Chemistry and Environment (Fellow). He acted as the Head of the Chemical Engineering Department, University of Calcutta, 2010-2012, 2017-2019. He also served as Hony. Secretary 2006-2007, 2014, 2018 and Hony. Treasure 2005, 2011-2013 in the Indian Institute of Chemical Engineers. He also served as Hony. Treasure 2017 to till date in Indian Chemical Society. He also acted as Chairman, Calcutta Regional Centre, Indian Institute of Chemical Engineers, 2012-2014. Hony. Secretary and Hony. treasure for several years in the Calcutta Regional Centre, Indian Institute of Chemical Engineers.

Engineering an Aqueous Energy Dense Manganese Dioxide|Zinc Battery to Challenge Lithium- Ion's Dominance

Dr. Gautam G. Yadav
Director of Advanced Battery Development, Urban Electric Power
gautam@urbanelectricpower.com

The current landscape of energy storage systems is dominated by lithium-ion batteries because of their high energy densities, and continuous improvement in performance through the last few decades for use in a number of applications. They certainly have been a boon for rapid societal development; however, they also have had major disadvantages like high cost, severe toxicity, high chances of flammability and ethical concerns about the use of cobalt. Aqueous batteries containing manganese dioxide (MnO_2) and zinc (Zn) have the theoretical capacities to deliver high energy densities comparable to some variations of lithium-ion batteries, have lowcost and toxicity, and high material abundance to be used as an alternative battery compared to the current status quo. However, MnO_2 and Zn have been highly irreversible and accessing close to their theoretical capacities has been very challenging. The current status quo in aqueous batteries has been to intercalate Zn and H-ions into layered structures to deliver modest capacities, which also has unfortunately resulted in limited energy densities. These layered structures, although novel, face limitations like their layered counter parts in lithium (Li)-ion batteries, where the capacity is limited to the host's intercalation capacity. Low voltage of ~1.1-1.4V is another Achilles heel of aqueous Zn-anode batteries, where it is simply not comparable to the high voltage properties of Li-ion. MnO_2|Zn batteries can compete with Li-ion because of its safe and abundant raw materials, nonflammable electrolyte and theoretical energy density, however, sufficient advances are required for it to be considered a truechallenger.

In this talk, we will present a new strategy to enable a new generation of energy dense aqueous- based batteries, where we exploit the conversion reactions of nanosized MnO_2 and Zn electrodes to extract significantly higher capacity compared to intercalation systems. Accessing the conversion reactions allows us to achieve theoretical capacities of 617mAh/g (~30mAh/cm^2) from MnO_2 and 810 mAh/g (~30 mAh/cm^2) from Zn anodes, respectively. The high areal capacities help to attain unprecedented energy densities of 210 Wh/L, which is the highest of all aqueous-based batteries. We will also present our work on identifying new Mn-based conversion compounds that give higher capacities and demonstrate its application in the case of small-scale automobile. We will also present our breakthrough work on breaking the 2V barrier in aqueous Zn batteries, where we have demonstrated for the first time in the field of energy storage >2.55V and 2.9V MnO2|Zn aqueous batteries capable of accessing the theoretical capacity, which can truly challenge Li-ion's dominance. Finally, we will briefly present our commercialization experience, and how market forces and application have guided the design and research of these batteries.

Bio-Data:

Dr. Gautam G. Yadav is a world-leading materials scientist and electrochemist, working as the Director of Advanced Battery Development at Urban Electric Power (UEP) in New York. He earned his doctoral degree in chemical engineering from Purdue University, where he specialized in synthesizing 1D complex metal oxide nanowires for thermoelectric applications and lithium(Li)-ion batteries. Prior to joining UEP, Dr. Yadav worked as a Senior Scientist at the CUNY Energy Institute, where he led the advancement of highly energy dense aqueous-based batteries based on manganese dioxide (MnO2) and zinc (Zn) as a replacement for the expensive and dangerous Li-ion batteries for grid-storage applications. He is the primary inventor of the reversible second-electron MnO2 technology and the breakthrough high voltage (2.45-2.8V) MnO2|Zn battery, which are published in Nature Communications and ACS Energy Letters, respectively. He has authored 19 publications and filed over 26 patents on MnO2|Zn technology, which have been licensed by UEP. At UEP, Dr. Yadav is leading a team of engineers and scientists to bring the second-electron MnO2 and high voltage (2.45-2.8V) MnO2|Zn battery to commercialization.

Carbon recycling: Gas fermentation turning sustainable carbon into fuels and chemicals

Dr. Sean Simpson
LanzaTech Inc. 8045 Lamon Ave, Skokie; IL. USA 60077
sean@lanzatech.com

Atmospheric CO_2 has accumulated to levels unprecedented since the Pliocene Epoch (> 2.6 million years ago). Although the effect of elevated atmospheric CO_2 on the climate has been predicted for 60 years, it wasn't until the 2016 Paris Agreement that nations agreed plans to abate atmospheric CO_2 release. These plans necessitate that sustainable carbon resources increasingly displace fossil resources as feedstocks for fuel and chemical production. The economic crisis triggered by the COVID-19 Pandemic has now added urgency to the demands for a move away from traditional polluting production systems. The opportunity being highlighted is that the public finance used to stimulate economic recovery be targeted at a technolgied that enable a circular, sutainable economic model. Numerous technology solutions have been proposed to enable this transition. Gas fermentation is the most recent of these. This technology uniquely offers a path to produce impactful volumes of sustainable fuels, chemicals and food from abundant, low value above ground carbon feedstocks.

LanzaTech is pioneering the commercialization of a gas fermentation process that allows the continuous production of fuels chemicals from gases at scale. Our first commercial plant is commissioned in China. Further commercial plants are in design or under construction with the process having been demonstrated with live feeds of waste gas from numerous industries and synthesis gas produced from agricultural wastes and municipal waste.

The potential role that gas fermentation could play in enabling a circular economic model has been enhanced through the development of a complete suite of synthetic biology techniques in gas fermenting organisms. This has led to an array of new chemical products being produced from gaseous feedstocks. In this way gas fermentation is a vital bridge in the effort to create value from waste streams as part of an increasingly circular economic model.

Bio-Data:

Dr Sean Simpson is current founder and Chief Science Officer for LanzaTech. H obtained his Masters from University of Nottingham (UK) and PhD from York University (UK). He has written over 20 publications and 200 patents. He has received a number of awards including the 2015 US Environmental Protection Agency(EPA) Presidential Green Chemistry Award, the 2014 Sanitarium, NZ Innovator of theYear Award, the 2013 Kea NZ World Class New Zealander in Science Award, and the2011 Ernst and Young Entrepreneur of the Year, New Zealand.

Robust, fluorine-free, proton- and hydroxide-conducting membranes for the hydrogen economy: from discovery to commercialization

Prof. Steven Holdcroft
Department of Chemistry, Simon Fraser University, Burnaby, BC, Canada V5A 1S6
holdcrof@sfu.ca

Ion exchange membranes which are capable of conducting protons or hydroxide ions have broadly been applied in electrochemical energy storage and conversion technologies. Electrochemical systems relying on alkaline-based active components possess unique advantages over their acidic counterparts but at the same time are associated with greater challenges. This presentation will focus on recent progress research trends incorporating these polymers into membranes, catalyst layers, and electrochemical energy storage and conversion devices. The challenges of integration that need to be overcome to meet critical requirements will be discussed, together with a summary and perspective for future directions.

Bio-Data:

Dr. Steven Holdcroft is President of the Canadian Society for Chemistry (CSC), a Professor of Chemistry, and former Chair ofthe Department. He holds a Tier 1 Canada Research Chair in Electrochemical Materials. He has research programs in ionic polymers, electrochemistry, and fuel cell technology, and has authored/co-authored of more than 300 peer-reviewed articles. He was the Technical Program Chair of Pacifichem 2010 and Technical Program Chair and Congress Vice-Chair of Pacifichem 2015. He serves on the Editorial Advisory Board of the journals Chemistry of Materials (ACS) and Energy and Environmental Science(RSC). In 2018 with three former students, he cofounded Ionomr Innovations Inc., a 25-person SFU spin-out company commercializing electrochemical membranes for clean energy applications. For services to the community,Dr. Holdcroft was awarded the Macromolecular Science and Engin¬eering Division Award of the Chemical Institute of Canada (CIC) and is a recipient of the Canadian Society of Canada RioTinto Alcan Award for contributions to Inorganic chemistry or electrochemical research. In 2018, he was recipient of the outstanding Alumni Award for Academic Achievement from his alma mater.

Applied Chemistry and Industry-Academia Interaction in India: A Personal Take

Dr. Amitava Pramanik
Society for Innovation & Development, Indian Institute of Science Bangalore
amitavap@iisc.ac.in

Indian Chemical Industry, thanks to the pioneering efforts of Acharya PC Ray back in 1892 and subsequently by several businessmen and entrepreneurs, grew significantly to about 180 billion-dollar business today, the sixth largest in the world. Although India is the third largest consumer of polymers and fourth largest producer of agrochemicals in the world and chemicals account for 12.5% of India's total exports, its contribution to global chemical industry is mere 3.4%. Bulk chemicals like petro- and agri-chemicals hold the limelight with small but significant contribution to fine and specialty chemicals like paints and colorants, flavours and fragrances, surfactants, chemicals for textile finishing, personal care, construction, water treatment, adhesives etc.

This discrepancy – if I may say so – lies largely due to the way Applied Chemistry is treated in the premier academic institutions in India as well as insignificant industry-academia interactions. Barring a few exceptions, most of the Chemistry Departments of reputed Indian Universities and Research Centres are unaware of the needs of Indian Chemical Industries. The industries on the same token hardly depend on inputs from Indian Academia. One can hazard a guess that the number of theses that provide the coveted PhD degree in Chemistry by all Universities across India to serve any of the Chemical Industries in India in a year is close to zero. It does not speak well for a nation that aspires to prosper on all aspects, certainly in Chemistry in which it possesses a long inheritance.

The talk will highlight some personal experiences on Industry-Academia relations and its output as well as a couple of practical recommendations on how this can be changed for the better.

Bio-Data:

Amitava Pramanik received his Ph.D. in Co-ordination Chemistry from Indian Association for the Cultivation of Science affiliated to Jadavpur University, Kolkata in 1993. After a couple of years of post-doctoral research in the same institute, he joined Unilever R&D in Mumbai in early 1995 and later moved to its Bangalore campus in 2004. He worked in various capacities, initially as a research scientist on specialty chemicals and later on novel synthetic materials including nanomaterials for Unilever's Home Care and Personal Care businesses. In his last role till October 2018, he was Unilever's global leader on the Strategic Science Group on Functional Materials. He has published ~40 papers and ~65 patents and worked on developing new products in the areas of specialty inorganics, micronutrients, photostable sunscreens, water purification, surface modification including non-stick surfaces, nanoparticulate antimicrobials, silk proteins etc. Since November 2018, he has been heading the Targeted Research Initiative in Society for Innovation and Development, Indian Institute of Science Bangalore.

Macromolecular Engineering in Self-healing Polymers using dynamic "Click" Chemistry; Preparation to Applications

Nikhil K. Singha
Rubber Technology Centre
IIT Kharagpur
West Bengal- 721302

It has been 100 years since Professor Herman Staudinger, the Nobel Laureate in 1953 published the first article on **"macromolecules"** in 1920 which has been the founding stone of today's **"Polymer Age".** Now polymers have been the most widely used industrial materials in the human life. Now-a-days polymers are not only used in household and commodity materials, but they are being used in hi-tech as well as in strategic materials. The major disadvantage of using the polymers is its longevity compared to other materials like metals and ceramics etc. Self-healing polymers have the inherent ability to heal the micro-cracks and scratches generated on them. In 2013, the World Economic Forum andthe Global Agenda Council announced the self-healing technology is one of the most important technologies in materials science and engineering.

Since the pioneering work of Professor Barry Sharpless in late 1990s, **"Click"** reactions have been wonderful synthons to prepare varieties of functional materials for different important applications. They have several advantages; they are carried out at mild reaction conditions with significantly high yields and with desirable stereoselectivity. In Polymer Science, **"Click Chemistry"** has been widely used to prepare smart self-healing functional polymer materials having application in advanced materials. In this case, different click reactions, like Diels-Alder reaction, Alder-ene reaction, ES-click reaction etc. will be discussed. Several examples will be shown how the tailor-made functional polymers prepared via controlled radical polymerization can be elegantly modified into self-healing polymer using different "click" reactions. These functional polymers were based on polyacrylates, polyurethanes, and commercial elastomers. The applications of these functional polymers were explored in self-healing materials, ultra-hydrophobic coatings and self-healable elastomers. This talk will delineate the preparation of different functional polymer materials as well as their applications.

Nikhil K Singha is a Professor at Indian Institute of Technology, Rubber Technology Centre and is also an associated faculty of School of Nano Science & Technology, Kharagpur. His research interest is in tailor-made functional polymers and elastomers, smart self-healing, self-cleaning, super-hydrophobic polymer materials, block, graft copolymers, electro-active, bio-active polymers and tailor-made polymer composites and polymer gels via controlled polymerization & their applications in self-healing and self-cleaning coatings, fire-retardant materials, space applications, advanced tyre applications, smart biomaterials, green & sustainable materials and process. He has received many awards like the Fellow of Royal Society Chemistry (FRSC), Prof. M. Santappa Award (2014) by Society of Polymer Science India (SPSI), MRSI Medal by Material Research Society of India (MRSI) (2013), Fulbright Senior Fellowship (2013), Fifth Polymer Foundation Award by Prof. Sukumar Maiti Polymer Award Foundation (2012), Visiting Scientist in University of Sheffield, UK with fellowship from Royal Society, London, UK (2006), in Institute for Polymer Research, Germany with INSA-DFG&DAAD fellowship (2008 & 2011) and in EPFL, Switzerland, Fellowship from Swiss Federal Institute (2009). He has supervised 19 Ph.D. students and is the editorial board member of European Polymer Journal and Frontiers in Chemistry (Polymer Section) Frontiers in Chemistry (Polymer Section). He has published in 170 peer-reviewed journals, 13 patents 10 book Chapters.

Fuel Quality & the history and role of fuel additives

David Claydon
Senior fuel additive technical advisor, Afton Chemical Ltd.
David.Claydon@AftonChemical.com

This paper will highlight the important role that fuel additives have played during the last ten decades to allow fuel specifications to be met in the most cost effective way. In addition we will discuss how multifunctional performance additives have enabled car manufacturers to met stringent environmental air quality requirements.

We will consider how fuel additives have and continue to improve the quality of fuels leading to:

1. Solutions related to environmental concerns
2. Economic benefits (imports/exports)
3. Retail competition and the production of branded fuels
4. Meeting the OEMs desire for better fuel quality in order to protect vehicle performance

Bio-Data:

David Claydon has a degree in applied chemistry and has had 40 years experience working in the fuel additive industry. His career began in 1980 working in the fuels technical service department of Paramins, a division of Exxon Chemicals based in the UK. This position involved supporting the application of cold flow improvers at refineries in order to help optimise refinery economics. In 1995 David moved to Ethyl Petroleum additives as technical service manager for fuel additives. This new role involved technical support and development for a wide range of refinery and performance additive packages for Europe and the middle-East. The company currently operates as Afton Chemical LTD.

David is currently a senior technical advisor for fuel additives and is this role plays an important part in ensuring that Afton Chemical has the appropriate technology to become and maintain its position as a market leader in performance additives for diesel fuel and to expand the company position in gasoline and heating oil additive markets. David has presented a number of technical papers and is well known and respected within the oil and additive industry.

An Entrepreneurial disruption to combat COVID 19 through Nanotechnology

Dr.Swapan Kumar Ghosh
Director, Nova Surface-Care Centre Pvt. Ltd.
swapan.ghosh@nsccindia.com

As declared by World Health Organization (WHO), presently the whole world is facing apandemic and a global crisis caused by a novel virus that was discovered to be the cause of a largeand rapidly spreading outbreak of respiratory disease, including potentially fatal pneumonia, inWuhan, China (starting January 9, 2020). The virus was provisionally designated 2019-nCoV and later given the official name SARS-CoV-2, the disease caused by the virus was officially named Coronavirus Disease 2019 (Covid-19) by WHO.The SARS-CoV-2 is an enveloped, positive sense, single-stranded RNA virus. Coronaviruses are so named because of their characteristic solar Corona (crown-like) appearance when observed under an electron microscope. This appearance is produced by the peplomers of the surface (or spike; designated S) glycoprotein radiating from the virus lipidenvelope1.The SARS-CoV virion is spherical with an average diameter of 78 nm.

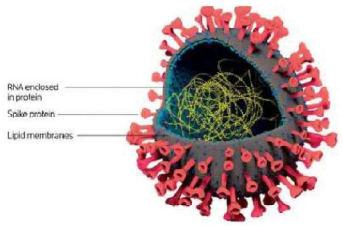

Figure 1: Anatomy of COVID-19 Virus (Figure from New Scientist Journal)

SARS-CoV-2 is delicate but highly contagious virus capable of spreading primarily from personto person around the world. It also spreads when an infected person cough or sneezed and a dropletlanded on a surface or object, a person when touches that surface has the virus on it, then touches nose, mouth or eyes, could pick it up. On the personal level hygiene measures are recommended to prevent the spread of disease, especially in the institutions where individuals are in contact with patients or contaminated fomites. Washing hands with soap and water or with alcohol based handrubs is effective for interrupting virus transmission. Although viruses don't grow on any nonliving surfaces but recent studies show Corona viruses can remain viable or infectious on metal, glass, wood, fabrics and plastic surfaces for several hours to days, irrespective of the surface looking dirty or clean. Though, the Corona viruses are relatively easy to destroy, using simple disinfectants like ethanol (62-71%), hydrogen peroxide (0.5%) or sodium hypochlorite (0.1%)[2] by breaking the delicate envelope that surrounds the tiny microbe. However, it's practically impossible to sanitizethe surfaces all the time and it doesn't guarantee that the surface won't get contaminated again. It's a much wiser solution in such a scenario if the surface can repel the pathogens, making it nonstick and/or 'sanitize by itself' by neutralizing the contaminated pathogens quickly, thus eliminating the possibilities of transfer of microorganism to human body and its subsequent spreads. Study shows that the spike glycoprotein of COVID-19 allows the virus to dock and bind to the ACE2 surface proteins of human epithelial cells in the respiratory track, thereby infectingthese cells.

Association of the COVID-19 spike glycoprotein with host ACE2 surface protein is acrucial step for infection.

Our research aim was to create surface coating with relatively low surface energy value which may repel the spike glycoprotein to anchor the surfaces of landing, also use of active chemicals those could inactivates the spike glycoprotein as well as viral nucleotides.

Literature survey shows that the nano-particles (NPs) of various metals and metal oxides like Zinc Oxide nanoparticles (ZnONPs)[3], Cuprous Oxide nanoparticles (CuONPs)[4], Silver nanoparticles(AgNPs)[5,6], Nano sized Copper (I) Iodide particles (CuINPs)[7], Gold nanoparticles on Silica nanoparticles (Au-SiO_2NPs)[8] and also some Quaternary ammonium cations commonly called QUATs[9] are very promising to inactivate virus and are well proven.

The product we have developed, NANOVA HYGIENE+™ as an antimicrobial coating for the surfaces like fabrics, plastics, metals and concretes contains the cocktails of non-migratory QUATs and positively charged AgNPs as bioactive nanoparticles and dispersing this into binderpolymers. This anti-microbial coating also shows extremely low surface energy value (>20mN/m)[10] and behaves as an omniphobic surface by repelling water and oil together. Contact angelswere >130^o and >50^o when measured against water and hexadecane as probes[10], respectively. This coating has proven test reports[11] on protection against bacteria pathogens up to 99.9% as per the global standard JIS Z2801. The coated surfaces also have evidence to work effectively against fungi[12] and algae pathogens.

From available published data in literatures, we can safely opine that NANOVA HYGIENE+™ would be a potential coating candidate to repel and inactivate Virus on the surface, hence could be a potential material to address the present problem of COVID-19 spread through surface touch. When tested in microbiology lab NANOVA HYGIENE+ ™ demonstrated successful performance against HUMACORONA VIRUS (229E) (A type Alpha Coronavirus) at NelsonLab, USA , Bovine Coronavirus (S379) (A type Beta coronavirus 1) from Eurofin, Italy, and MS2, RNA virus a surrogate virus in place of Picoma viruses such as Poliovirus and humanNorovirus from accredited NABL lab in India and products show efficacy of > 99% while tested as per global standards ISO, JIS, EN and AATCC. Finally, we have tested for its antiviral efficacy on SARS-CoV-2 (virus responsible for COVID-19 disease) and obtained very successful datawith efficacy >99% in after 3 months old surface. Further NANOVA HYGIENE+ ™ has been tested for its nontoxic properties as per globalstandard of Nontoxic Acute Dermal Skin Irritation Report (OECD 404) and global leachingtest for food contact US FDA 175.300 and these test results confirms that the technology is nontoxic and safe to use.

Based on the results, Its shows that NANOVA HYGIENE+ TM has numerous applications virtually for all surfaces like fabric (mask, gloves, doctor coats, curtains, bed sheet), metal (lifts, doors handle, nobs, railings, public transport), wood (furniture, floors and partition panels), concrete (hospitals, clinics and isolation wards), plastics (switches, kitchen and home appliances) and potentially could save many lives.

Product is now successfully commercialized, and distribution started in Indian and some of the foreign markets.

Dr. Swapan Ghosh, the founder of Nova surface-care Centre Pvt Ltd. is a polymer scientist with over 30 years of research experience in academia and Industrial R&D. Dr. Ghosh worked as Assistant Professor in Venture Business Laboratory of Yamagata University in Japan and, after moving to India, worked in reputed Indian companies including Pidilite, Asian Paints and Shalimar Paints. Dr. Ghosh more than 100 innovative products and published more than 30 scientific papers in international peer- reviewed journals and have 8 product patents in his credential. He has also guided two PhD dissertations in affiliation with Bombay IIT and ICT, respectively.

Crude Oil to Chemicals Conversion –Molecular Management Strategy

Dr. Madhusudan Sau
Chief General Manager (Refining Technology), IndianOil R&D Centre, Faridabad
saum@indianoil.in

Globally petroleum refiners are adopting Crude Oil to Chemical (COTC) process technologies for addressing chemical/petrochemical demand growth and maintaining sustainability in the emerging scenarios like e-mobility, alternate energy sources, etc. In the past century energy potential of crude oil has been unfolded and maximizing fuel yield was the primary focus for every refiner. About 5-10% crude gets converted to Petrochemicals in current day fuel refinery with certain extend of integration for petrochemicals. To unleash the huge chemical potential of crude oil, molecule level management is now getting prime importance and extensive research activities are taking place across the globe for developing novel processes focusing to maximize chemical yield from crude oil. Life cycle assessment of molecule tracking each and every molecule, starting from its generation point to its end application, is also getting importance. Life cycle assessment and molecule management together need to be applied for developing new process to reengineer the molecules towards more useful purpose. Further, it will be also be beneficial for reducing carbon footprint as well.

IndianOil's efforts are geared towards in-house technologies aiming to maximize light olefins while producing BTX (Benzene Toluene and Xylene) precursor. IndianOil's COCT configuration is the potpourri of conventional and new processes technologies. Based on the molecule management, the conventional and new process technologies have been configured and placed in such a manner so that the targeted molecules can be fed to the appropriate process units for yielding maximum chemical potential. INDMAX technology is developed which employs circulating fluidized bed reactor and unique catalyst recipe of medium pore and pentasil based zeolites with hierarchial pore structures for sequential breaking of hydrocarbon C-C bonds for producing very high light olefins. INDALIN process is developed for cracking of naphtha molecules using lesser energy than Steam cracking with high light olefin yields. A novel technology, 'indLPet' is developed to convert di- and tri- aromatics of LCO (Light Cycle Oil) streams, which would have burned off as diesel, to Toluene Xylene isomers and C9-aromatics, exemplifying molecule management. Efficient residue management is achieved through residue hydrocracking process, 'indResid' with a novel catalyst and reactor configuration to effect high degree of residue conversion (~95 wt%) to distillates, which further can be converted to olefins. This paper describes the features of the some of the IndianOil technologies, which are an integral part of COTC configuration for higher yields of Chemicals.

Bio-Data:

Dr. Madhusudan Sau is a Chemical Engineer, MTech from IIT Kanpur and PhD from University of Akron, USA. He has been working in the R&D Centre of Indian Oil Corporation past 28 years and currently he is Chief General Manager (Refining Technology). His area of work includes new Process and

Catalyst Development, Process modeling and Technical services, troubleshooting and optimization, Catalysts selection in the area of Refining Technology.
His major contributions are Development, Scale-up and Commercialization of indeDiesel technology & Hydro-teating Catalysts, Process optimization of refinery process units to improve middle distillates yield and GRM improvement. He has published over 36 papers, filed 140 Patents and has 6 Awards in his credit.

Advanced Characterization for Industrial Catalysis

Dr. Shelly D Kelly
Sr. Manager Advanced Characterization, Honeywell UOP
Shelly.Kelly@Honeywell.com

This paper will survey several critical techniques used to unravel the complex nature of industrial catalysts. Foremost, an industrial catalyst must have high activity and selectivity and be regeneratable with long lifetime. The catalyst needs to be strong so as not to fall apart but also contain macro and micro porosity to allow diffusion of feed components in liquid and/or gas phase. Residence times for target molecules can be adjusted by changing the porosity to produce the desired products with high selectivity. The catalyst active sites need to be resistant to poisons such as sulfur, iron and other trace metals. Ideally industrial catalysts are resilient not only under normal operating conditions but also through occasional upsets. Although there are many tools required to understand these properties, x-ray absorption spectroscopy remains one of the few to probe active metal sites during operando (working state) conditions. This is made possible by the high penetration power of x-rays that can probe catalyst active sites through reactors and gas/liquid feed components and quantitively measure the local atomic environment of active metals. We will present a few examples of how Advanced Characterization for industrial catalysts help understand their complex nature.

Bio-Data:

Dr. Shelly D Kelly received her PhD from the University of Washington in Physics in 1999. Currently, she is senior manager of X-ray, Modeling and Spectroscopy group at Honeywell UOP. Her research is focused on understanding catalysis, molecular sieves and sorbents for petrochemicals and fuels industry with emphasis on Advanced Characterization techniques, including operando and in-situ X-ray Absorption Spectroscopy (XAS). She has participated as a lecturer in XAS workshops in the U.S. and abroad, reviewer of general user proposals for access to synchrotron user facilities, and as beamline advisory team member for the Inner Shell Spectroscopy (ISS) beamline at NSLS-II. She is an executive member of Materials Research Collaborative Access Team (MR-CAT) beamline at Advanced Photon Source. Shelly has contributed to 83 peer reviewed papers, 5 book chapters and 1 U.S. Patent.

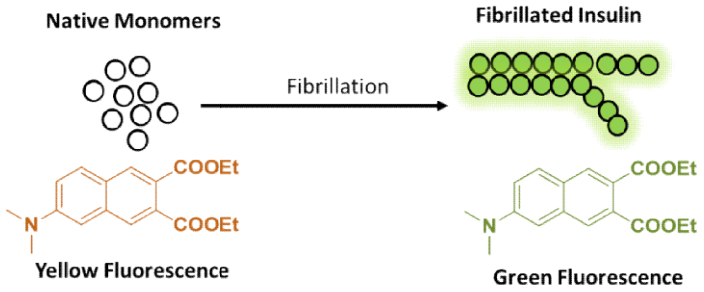
DMNDC- An intramolecular charge transfer dye for the detection of amyloid fibrils

Anirban Das,[a] Tanoy Dutta,[a] Apurba Lal Koner, [a] Ishu Saraogi[*,a,b]
[a]Department of Chemistry, IISER Bhopal,[b]Department of Biological Sciences, IISER Bhopal,Bhopal Bypass Road, Bhopal – 462066, Madhya Pradesh, INDIA
(E-mail: anirban16@iiserb.ac.in)

Proteins are large macromolecules involved in various functions in the body including DNA replication, catalyzing metabolic reactions and so on. The misfolding of proteins leading to aggregate formation is associated with various diseases like Alzheimer's, Parkinson's, Type-II Diabetes.[1]Researchers are always on the lookout for novel molecules which can inhibit the aggregation of proteins as a means to prevent these diseases. Apart from inhibition of aggregation, the ability to detect these aggregates plays an important role to diagnose these diseases at an early stage and prevent them from having far reaching effect on human beings. Till date, Thioflavin-T(ThT) has been used as a gold standard for monitoring fibrillation of proteins due to the huge enhancement in fluorescence intensity upon binding to fibrils. However, ThT suffers from disadvantages like small stokes shift and also shows interference while studying fibrillation kinetics in presence of small molecules.[2] Moreover, the use of intrinsic fluorescence of tryptophan and tyrosine as a means to study aggregation has not been much successful due to their inherent weak quantum yield.[3] This has necessitated the researchers to develop small fluorogenic molecules for monitoring amyloid formation.

In our study, we have used insulin as a model protein for studying amyloid related diseases, which is known to undergo fibrillation at the site of repeated injections in diabetic patients and also during its industrial process. Here, we describe DMNDC as an intra-molecular charge transfer dye which exhibited varying fluorescence properties according to its surroundings. As an alternative to ThT, DMNDC was found to be an excellent probe for the detection of amyloid fibrils with alarge stoke shift, a huge enhancement in fluorescence, and an excellent blue shift (~70 nm) in fluorescence upon binding to fibrils.[4] DMNDC was found to exhibit no significant effect on insulin fibrillation when used in molar excess as an inhibitor. This suggested the use of DMNDC as an amyloid sensor and not as an inhibitor.



Interestingly, DMNDC was later found to efficiently detectamyloid formation of α-synuclein protein associated with Parkinson's disease. Additionally, the efficient cellular internalization of DMNDC and low cytotoxicity makes it an efficient molecule to be used in biological systems.

Effect of Heavy Metal Concentration in Ground Water Due To Fly Ash At Janghir Champa Region in Chhattisgarh

Manoj Kumar Ghosh* and HarshaTiwari**
*Associate professor, Department of Chemistry
** Research Scholar, Department of Chemistry
Kalinga University, Naya Raipur (C.G.) – India.
E-mail- hupadhyay.0709@gmail.com

The present study focused on the groundwater contamination due to fly ash disposal of coal-fired thermal power plant into a non liner ash pond. Tendubhata were selected as study site around ash pond of Marwa thermal power plant. Groundwater samples were collected on random basis using composite sampling method. Ten heavy metals like Ca, Cu, Cd, Cl, Zn, Pb, Ni, Cr, Mn, and Fe were detected in groundwater samples in different areas of janghir champa. Heavy metal concentration is detected by AAS was used for groundwater assessment. The observed results revealed the exceeding value of heavy metals prescribed by WHO, Indian standard and CG standard for groundwater.

Keywords: Groundwater, Fly ash, Thermal power plant, ash pond, heavy metal.

Efficacy of Vitamin C in Prevention of Methemoglobinemia Caused by Nitrate Containing Drugs in Diabetics and Nondiabetics

Debashree Das
Department of Chemistry, University of Calcutta, 92 APC Road, Kolkata 700009
Email ID: debashreedas2@gmail.com

The drugs containing nitrates like isosorbide dinitrate, isosorbide mononitrate and glyceryl trinitrate, etc., trigger the oxidation of hemoglobin which is manifested in the pathological disorder named methemoglobinemia. It was considered interesting to investigate the preventive roles of vitamin C towards the toxic effects of nitrate containing drugs used for the prevention of angina. The aim of the present work is to find whether these drugs need to be administered with special care to diabetic patients who are more prone to develop methemoglobinemia.Vitamin C (500mg/day) was administered orally to reduce the methemoglobin (metHb) level in both the diabetic and nondiabetic patients consuming nitrate containing drugs regularly, keeping diabetic and nondiabetic patients not on nitrate drugs as control. MetHb level was found to be lower after the treatment with vitamin C for 30 consecutive days than that before the trial with statistically significant two tailed p value. Additionally, fasting insulin level was also found to decrease after 4 weeks of consumption of vitamin C with moderate lowering of fasting serum glucose level as well, indicating a higher insulin sensitivity for the treated patients.

Gallium doped TiO_2 nanoparticles for adsorption - desorption behavior of tea polyphenols

Pritam Singh, Subhasish Ghosh and Kamalika Sen*
Department of Chemistry, University of Calcutta, 92, A. P. C. Road, Kolkata 700009, India
Email: singhapritam1994@gmail.com, *kamalchem.roy@gmail.com

Tea polyphenols have unique properties in the field of nutritional, medicinal and fine chemical industries. However, since they remain assembled together in the tea extract, methods to purify and separate them from one another become a challenging task. Chromatography, membrane separation, precipitation, etc have been reported to have served the purpose. Adsorption based methods are mostly favored for their clean technology. The present work deals with the synthesis of pure and gallium doped TiO_2 nanoparticles followed by adsorption and desorption study of different tea polyphenols. The TiO_2 nanoparticles were synthesized by using titanium isopropoxide as a source of titanium and pluronic F-68 as a surfactant. The gallium doped TiO_2 was prepared by taking the ratio of Ti:Ga equal to 1:10 and 1:20. Finally calcination at 400 and 600 °C was performed to get the pure TiO_2 and Ga doped TiO_2 material. Then these materials were characterized using different analytical techniques like, N_2 adsorption-desorption and Brunauer–Emmett–Teller (BET) method, Fourier Transform Infrared Spectroscopy (FTIR), Powder X-ray diffraction (PXRD), solid state UV-vis spectroscopy, transmission electron microscopy, etc. Finally catechin, gallic acid, epigallocatechin gallate and caffeine were chosen as tea polyphenols to study the adsorption and desorption behavior of the prepared titania materials. The adsorption experiment was studied upto 7 hour with varying pH range from pH 1 to pH 9 using all the six set of titania nanoparticles. The adsorption data suggested that, the 1:10 Ga doped TiO_2 nanoparticle calcined at 400 °C (indicated as Set 3 TiO_2) could adsorb catechin and gallic acid upto 100 % for 5 h shaking in pH 5 medium. Whereas, 1:10 Ga doped TiO_2 nanoparticle calcined at 600 °C (indicated as Set 4 TiO_2) could adsorb epigallocatechin gallate upto 99 % for 5 h shaking at pH 1 medium. The adsorption of catechin, epigallocatechin gallate and gallic acid followed Langmuir Isotherm. Water was taken as desorption medium and gamma radiation, shaking, sonication and UV radiation were used to stimulate the desorption process. The conventional Folin –Ciocalteu method was used to examine the desorption behavior of the highest adsorbed material. The desorption study showed that from Catechin and gallic acid adsorbed Set 3, Catechin was not desorbed at all while gallic acid could be desorbed using 72 h irradiation with gamma energy (dose rate1.313 KGy/h). The Set 4 sample with epigallocatechin adsorbed in it could be desorbed upto 96 % under sonication for 30 min. Thus, the polyphenols could be selectively separated from one another using mild desorption conditions and hence can be used for further applications.

Clinical Impact of Caffeine on the Diabetic Patient'sSerum: A Spectroscopic Study

Bhavya Srivastava[1], Souvik Sen[2] and Kamalika Sen[1]*
[1]Department of Chemistry, University of Calcutta, 92 A. P. C. Road, Kolkata 700009, India
21F, Raja Subodh Chandra Mullick Road, Jadavpur, Kolkata, 700032, India
Email: bhavya.srivastava0@gmail.com, kamalchem.roy@gmail.com

Diabetes is a leading cause of diabetic neuropathy(DN), but its harmful consequences are avoidable with early detection and treatment.DN is associated with the accretionin oxidation of sorbitolwhich is potential sources of hyperglycemia-induced oxidative stress[1,2].Thussorbitol measurement in serum can serve as a good indicator in the diagnosis and monitoring of the diabetic complications[3]. To remove the surplus sorbitol from the body, proposed binding of sorbitol with caffeine (1,3, 7-trimethylxanthine) was investigated.Isothermal titration calorimetric (ITC) experiments clearly indicate binding sites (i.e., 3.89, 1.40, 2.07) between sorbitol and caffeine at the complexation ratio of 1:1.2, 1:1.5 and 1:3. Blood glucose level was measured spectrophotometrically where glucose was oxidised to gluconic acid, and produced H2O2 in turn oxidizes a dye (4-amynoantipyrine) in a quantitative enzyme-catalysed reaction[4].The blood glucose level obtained from non-diabetics groups were compared to a similarly aged group of diabetics treated aggressively with caffeine doses (10 mmol L−1) adjusted for changes in blood glucose in order to achieve and maintain serum sorbitol level.Caffeine helps in interpreting screening and development of DNby fluorometric enzymatic analysis of sorbitol level on the diabetic patients (mean age 44± 0.43 years, range 24-64 years). Further the effect of caffeine is compared with a non-diabetic subject is established by UV-Vis (λ_{max} = 340 nm) and fluorescence spectrophotometry.Association constant (K= 214 M^{-1}) is determined for sorbitol by NADH concentrations.Caffeine can be helpful in both reducing the sorbitol level and also chances of development of DN by introducing small doses of caffeine.The sensitivity of this screening program in detecting diabetic neuropathy disease compared with the serum of healthy adults has been checked and found efficient and 80%accurate.The present method can be helpful in suggesting a plausible remediation for treating DN.

AO-6

γ-Irradiated Selenium Nanoparticles for Optical Sensing of a Cancer Biomarker

Shalmali Basu, Debashree Das, Kamalika Sen*
Department of Chemistry, University of Calcutta, 92 APC Road, Kolkata 700009, India
*kamalchem.roy@gmail.com, shalmalibasu04@gmail.com

Early detection and supervision of cancer using cancer biomarkers is a well-focused area in recent research and development field. Carcinoembryonic antigen (CEA) is a protein present at very low levels in the blood of adults (<2.5 ng/ml in non-smokers and <5.0 ng/ml in a smoker). The CEA blood level may be increased in certain types of cancer and in certain non-cancerous conditions. A CEA test is most commonly used to diagnose colorectal cancer. Low sensitivity and specificity of different established methods (electrochemiluminescence, potentiometry, electrical, electrochemical methods, etc.,[1] demand special attention. In this novel study, a simple, rapid, efficient and cost-effective method is reported using selenium nanoparticles (SeNP) for the optical detection of CEA. Results establish efficacy of prepared SeNP to sense CEA in serum medium even at its low concentration using UV-visible spectroscopy. γ-irradiated (24h) Se nanoparticles (γ-SeNP) was found to have higher sensitivity towards CEA compared to non-irradiated SeNP as it could deliver higher signal enhancement owing to its higher surface activity and charged nature.Results also indicate that presence of glucose, cholesterol and bilirubin in serum does not interfere with CEA sensing. In fact, significant increase in detection thresholdwas achieved in presence of glucose, cholesterol, bilirubin and in their combined physiological conditions as the limit of detection (LOD) obtained is manifold less as compared to an otherwise healthy condition.Thus, this detection method could also be applied efficiently to the patients having these comorbidities. Results make this optical method to be a sensitive as well as a specific one for the superior detection of biomarkers. This proposed approach is practical and holds the potential for clinical diagnosis of CEA.

Efficiency of Resin bound gold nanocomposite materials en-route of dye adsorption from aqueous solution

Anushree Saha*, Manas Kanti Deb
School of Studies in Chemistry, Pt. Ravishankar Shukla University, Raipur-492010, Chhattisgarh
Email: anu.saha011@gmail.com

The citrate-capped gold nanoparticles (AuNPs) and anion exchange resin (activated Amberlite XAD-4) were used for the formation of resin bound gold nanocomposites (R-Au NCs), to remove the dyes from water sample due to the large surface area to volume ratio. Adsorption of commercial reactive cationic dye, methylene blue (MB) from water, onto the R-AuNCs was carried out in this present work. Fourier transform infrared (FTIR) spectroscopic and UV-Vis spectrophotometric analysis were performed to confirm the adsorption phenomenon onto the surface of the R-Au NCs and also characterized by sanning electron microscopy with energy dispersive X-ray analysis and X-ray diffraction analysis. The IR absorption peaks for nanocomposites was obtained at 3451 cm^{-1}, 2923 cm^{-1}, 1717 cm^{-1}, 1600 cm^{-1} and 1445 cm^{-1}, which is corresponded to the stretching vibration of O-H, symmetric stretching of C-H, stretching vibration of C=O, and stretching vibration of C=C respectively. The calibration curve gave a higher linearity in the range between 5-25 μgL^{-1} with correlation coefficient (R^2) 0.989 and limit of detection of 0.2 μgL^{-1}. The percentage adsorption efficiency (Q_e) was obtained to be 77.64 %. The advantage of the present method is easy, low cost and efficient for monitoring of the removal of dye from water sample.

Design of D-mannitol and PPG#400 Based Aqueous Biphasic System for Extraction of Drugs Recommended in Covid-19

Laboni Das[1], Sankar Prasad Paik[2] and Kamalika Sen[1]*
[1]Department of Chemistry, University of Calcutta, 92 APC Road, Kolkata 700 009, India
[2]Department of Chemistry, Sundarban Mahavidyalaya, Kakdwip 743347, India
kamalchem.roy@gmail.com, labonids270692@gmail.com

Aqueous biphasic system (ABS) offers a green alternative to the traditional liquid-liquid extraction system in which toxic, volatile and inflammable organic solvents are used1. ABS is generally composed of two mutually incompatible aqueous solutions of polymer-polymer, polymer-salt, salt-salt, carbohydrate-polymer etc., at a certain thermodynamic condition[1,2]. According to literature, the carbohydrate-polymer system is one of the least studied systems. Carbohydrates have the advantage of having nonionic, nontoxic, biodegradable nature with cheap and easy availability. In this work, a polymer-carbohydrate based ABS consisting of 18% (w/v) aqueous solution of D-mannitol and PPG#400 (100%) has been constructed at 309 K. The phase diagram of the newly formed ABS was plotted using Merchuk equation. The advantage of the newly designed D-mannitol based ABS is that it is free of ionic materials in contrast to most of the previously reported ABSs which are either composed of highly concentrated ionic salts or ionic liquids. The present ABS was found suitable to extract L-ascorbic acid (Vit-C), Ivermectin and Doxycycline which are widely recommended for the current treatment of COVID-193-5. The extractions are studied at different pHs (3, 5 and 7) of D-mannitol rich phase. The polymer rich phase of the ABS was collected for spectral study to determine the extraction percentages. The percentages of extraction of L-ascorbic acid are 19%, 21% and 30% respectively at pH 3, 5 and 7. The percentages of extraction of Ivermectin are 79%, 84% and 87% respectively at pH 3, 5, 7 and 62%, 68% and 69% respectively for Doxycycline extraction.

Nitrogen-Doped Carbon Quantum Dots-MnO_2 Nanowires Based Fluorescence Probe for Detection of Cholesterol, Glutathione, AChE and Pesticide

Lakshita Dewangan, Manmohan L. Satnami
School of Studies in Chemistry,
Pt. Ravishankar Shukla University, Raipur (C.G.) – 492010
lakshitadewangan06@gmail.com

Cholesterol and glutathione has attracted extensive attention because in human fluids is clinically important analytes and their sensitive detection is significant in diagnosis. In this study, FRET based fluorescence "switch-off-on-off" of nitrogen doped carbon quantum dots (N-CQD) in the presence of MnO_2 nanowires have been successfully applied to fabricate a fluoremetric biosensing platform for detection of cholesterol, glutathione, AChE and pesticides. The cholesterol and ATChI could be oxidised by cholesterol oxidase (ChOx) and acetylcholinestrase (AChE), in accompanied with the formation of H_2O_2 and thiocholine intermediate respectively. Thus H_2O_2, thiochoine disulfide and glutathione disulfide produced from oxidised glutathione resulted in the decomposition of MnO_2 nanowires (brown) to give Mn^{2+} ions (colorless), which induced the absorption of MnO_2 nanowires decreased and the fluorescence of N-CQDs increased consequently gives sufficient recovery of fluorescent signal. Vice versa fluorescence intensity is decreased in presence of chlorpyrifos pesticides due to inhibition of AChE. The sensing platform shows a sensitive response to cholesterol, glutathione and chlorpyrifos pesticide in linear regression ranges of 10 to 150 nM, 20 to 200 nM and 1 to 35 µM, with the detection limit and LOQ of 16.06 nM, 8.47 nM, 7.40 µM and 50.32 nM, 25.67 nM, 22.43 µM are obtained by fluorescent method. This promising strategy was successfully applied in monitoring the cholesterol, glutathione and pesticide such a consecutive recognition process provides valuable insights for bio-analysis.

Keywords: N-CQD, MnO_2 Nanowires, Cholesterol Oxidase, Cholesterol, Glutathione, Acetylcholinestrase, Chlorpyrifos.

Separation of radioarsenic, ^{71,72}As from alpha particle irradiated gallium oxide target

Nabanita Naskar*, Susanta Lahiri
Saha Institute of Nuclear Physics, 1/AF Bidhannagar, Kolkata-700064
g.nabanitanaskar94@gmail.com

Importance of no-carrier-added (NCA) radioisotopes is well-known in nuclear medicine. Radioisotopes with suitably short half-lives have bio-medical applications. Few arsenic radioisotopes have suitable nuclear properties applicable for imaging and treatment. ^{74}As (17.77d), ^{72}As (26.0h), ^{71}As (65.3h), ^{70}As (52.6min) are potential isotopes for positron emission tomography (PET) or single photon emission computed tomography (SPECT). ^{72}As-^{77}As can form a theranostic pair, where ^{72}As act as imagingand ^{77}As as radiotherapeutic agent. ^{71,72}As was produced by irradiating gallium oxide target by 46 MeV α-partcles. ^{71,72}As was separated from target matrix by liquid-liquid extraction (LLX) using tricaprylmethylammonium chloride (Aliquat-336) and trioctyl amine (TOA) diluted in cyclohexane. Complete separation was observed at 2 M HCl + 0.01 M Aliquat-336 and 3 M HCl + 0.1 M TOA. High separation factors could be observed between bulk Ga and NCA As radionuclides. Bulk gallium was completely extracted in the organic medium by both the anion-exchangers, TOA and aliquat-336. No-carrier-added ^{71}As was obtained in the aqueous medium without any contamination from the target matrix at best conditions. This radiochemical separation is simple and fast for separating radioarsenic from gallium oxide target. Since NCA ^{71}As was present in aqueous medium, the radioisotope can be directly used for further applications.

Non-contact laser based spectroscopicanalytical technique for condition monitoring of industrial materials

Aparna Neettiyath
Department of Electronics Engineering, IIT (ISM) Dhanbad, Jharkhand, India
aparnan@iitism.ac.in

Quantitative atomic-analysis relies on atomic absorption/ emission/ fluorescence principles. Laser induced breakdown spectroscopy (LIBS) is a novel atomic-analysis technique that uses laser produced plasma for generating aerosol/vapour as well as ionization, which is attractive for industrial materials. It does not need any sample preparation like acid digestion and is non-contact and almost non-destructive.LIBS was tested for several industrial materials including transformer-insulation, Si-R insulation and coal quality-monitoring.

Immature failure of transformers due to Cu-contamination of oil impregnated pressboard (OIP) insulationhave been threatening power industry (also reported by CIGRE) [1,2]. LIBS has been tested successfully for condition monitoring of OIP and identifying the level of degradation using several parameters such as intensity, plasma persistence time and depth of diffusion [3-6]. Figures 1a and 1b show the LIBS spectra of virgin and aged OIP material, indicating several Cu emission lines detected. Industry OIP sample was tested using LIBS by large-area Cu-intensity imaging (Figure 1c).Innovative variations of LIBS, such as molecular LIBS and spatially resolved spectrally integrated LIBS were also found to be useful for better understanding of the degradation and improved the utility of LIBS as an analytical technique [7-8].LIBS was also found to be useful in identifying presence of rare-earth elements in coal and quality-monitoring.

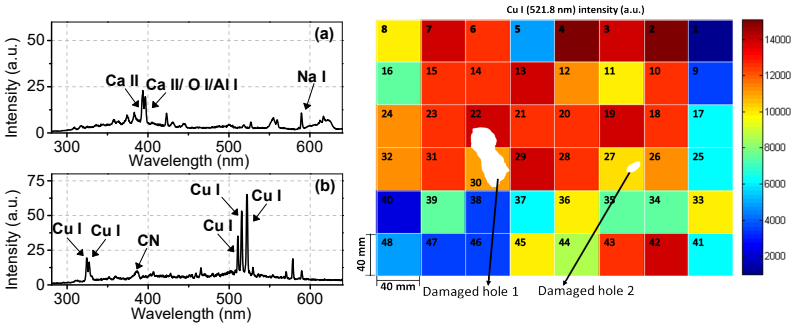

Figure 1 UV-Vis LIBS spectrum of (a) virgin (un-aged) OIP material (b) aged OIP matrial (c) LIBS intensity map of failed OIP insulation collected from TNEB

Developing scenario of titania-based building materials for environmental remediation

[1]Subhasish Ghosh, [1]Rituparna Patra, [2]Dipanjali Majumdar & [1]Kamalika Sen*
[1]Department of Chemistry, University of Calcutta, 92, APC Road, Kolkata-700009
[2]National Environmental Engineering Research Institute, Kolkata Zonal Lab, West Bengal-700107
rituparnab41994@gmail.com

The present review article is aimed at analysing the different aspects of titania-modified building materials towards environmental remediation. The possibility of degradation of different toxic environmental pollutants like VOCs and NOx by the titania-modified paints, cements and other building materials has been discussed. The major role of titania resides in its photocatalytic activity that renders the materials' potent for degrading these obnoxious compounds. The application of TiO_2 both in small and in large scale and the mutual relationship of the amount of TiO_2 with the amount of main building block constituents are discussed in detail. Application of daylight or lamplight, energy, time, and atmospheric conditions has also been dealt with. This review article solely focuses on titania-incorporated building blocks and is an endeavour to propagate a new horizon for our future pollution-free perspectives. Several environmental and product-related parameters that affect the efficacy of these modified matrices have been taken up. The present scenario in the industrial fields has also been assessed. Finally, a critical view is also presented that highlights the shortfall and areas open for further research and development in this particular field.

Colorimetric and paper-based sensor for selective detection of lead using PVA functionalized silver nanoparticles: Experimental and theoretical approach

AP-1

Bhuneshwari Sahu* and ManasKanti Deb
School of Studies in Chemistry, Pt. Ravishankar Shukla University, Raipur, CG-492010, India
Corresponding author: bhuneswarisahu90@gmail.com

We report a plasmonic colorimetric sensing strategy using polyvinyl alcohol (PVA) modified silver nanoparticles (AgNPs) and paper-based analytical devices (PADs) for selective detection of lead (Pb). Method is based on the measurement of red shift of localized surface plasmon resonance (LSPR) absorption band of AgNPs/PVA in visible region after the addition of Pb(II) using UV-Vis spectrophotometry and color intensity of PADs was recorded with Smartphone followed by the processing in ImageJ software. The mechanism of color change and red shift ($\Delta\lambda$) of LSPR band from 410 nm to 550 nm is due to the interaction of Pb(II) ions towards the PVA through strong ion-dipole interaction perturbing the stability AgNPs which further directed the aggregation of particles. The calibration curve gave a good linearity in the range of 20-1000 μgL^{-1} with limit of detection (LOD) of 8 μgL^{-1} by colorimetry and 50-1000 μgL^{-1} with LOD value of 20 μgL^{-1} using PADs. The advantages of using AgNPs/PVA as plasmonic colorimetric probe and PADs found to be simple, low cost and selective for determination of lead from surface water and industrial waste water samples.

Keywords: Silver nanoparticles, PVA, colorimetric probe, paper based analytical devices, lead, water samples.

Mistletoes are extremely important plants and their extracts have been widely used as a complementary medicine towards cancer therapy. In this context, we have studied the leaves of a South Indian Mistletoe, Macrosolen capitellatus (Wight & Arn.) Danser, a parasitic plant belonging to family Loranthaceae. A bioassay-guided isolation and LC-MS dereplication strategies have led to the isolation of pinocembrin-7-O-[4", 6"-(S)-hexahydroxy diphenoyl (HHDP)]-β-D-glucose (1).This is the first report showing the presence of 1 not only in this plant but also in the genus Macrosolen. In this study, the aforementioned parasitic plant was collected from two different host plants, Mangifera indica and Phyllanthus emblica, which were extensively studied chemically by various research groups. We have observed that 1 is present in both samples of M.capitellatus, while a thorough literature search showed that this compound 1 has not been reported from either Mangiferaindicaor Phyllanthusemblica. These observations indicated that the producer of 1 is nothing but parasitic plant M.capitellatus. This compound has shown moderate anti-proliferative activity against MCF-7 cell line (IC 50 value-15 µM). A computational protein binding study has been performed on 1 against 25 crystallographic proteins of the BRCA-1 gene of breast cancer. The results showed interactions having - 9.33 and-8.99kcal/mol binding energy with the proteins IDs 1T15 and 1T29 respectively; which suggests that this scaffold has the potential to develop further. Macrosolencapitellatus(A) Leaves and (B) stems Bio-assay-guided isolation Isolation of compound Invitro cytotoxicity assay on MCF- 7 Molecular docking Spectral analysis Dereplication of known compound by LC-HRMS referring dictionary of natural products

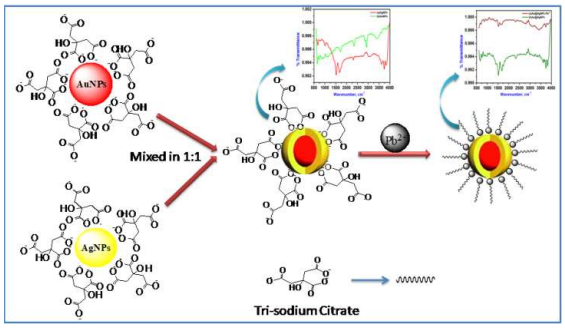
Fabrication ofAu@AgBimetallic Nanoparticles for Selective Detection of Lead in Onion Sample

Sushama Sahu[a] and Kallol K. Ghosh[a]
[a]School of Studies in Chemistry, Pt. RavishankarShukla University, Raipur-492010(C.G.), India
Email Id: sushamasahu02@gmail.com

Here, we report a novel and facile Gold-Silver (Au@Ag) colorimetric method for determination of leadion (Pb^{2+}) in onion(*Allium cepa* L.) samples collected from different areas of Chhattisgarh. Au@Ag bimetallic nanoparticles (BiMNPs) were chosen as sensing probe to demonstrate and optimize the method for determination of Pb^{2+} using UV-Vis, transmission electron microscope (TEM), diffuse reflectance fourier transform infra-red (DRS-FTIR) spectroscopy and energy dispersive X-ray spectroscopy (EDX). The DRS-FTIR transmittance peak observed for Au@AgBiMNPs at 1500-1700 cm^{-1} was enhanced by addition of Pb^{2+}. It has also been confirmed by shifting ofplasmon band towards higher wavelength. This shifting of bandhave been further used for the optimization of different analytical parameters and for the determination of Pb^{2+} *via.*Au@AgBiMNPs. A linear calibration curve obtained by this experiment with linearity range, limit of detection and limit of quantification was as 10-100ng mL^{-1}, 5.28ng mL^{-1} and 17.62 ng mL^{-1}, respectively. The advantageous features of the proposed method are their sensitivity, selectivity and reproducibility to easily determine Pb^{2+} in onion samples in presence of other heavy metal ions.



Keywords: Au@Agbimetallic nanoparticles, lead ions, colorimetric sensor.

OP-3

Basic and advanced logical concept derived from surface enhanced infrared spectroscopy (SEIRS) as sensing probe for analysis of chemical species: A brief review

Shubhra Sinha*, Manas Kanti Deb
School of Studies in Chemistry, Pt. Ravishankar Shukla University, Raipur-492010 (C.G.)
Email: shubhrasinha2910@gmail.com

Infrared spectroscopy is an immensely important technique whose major concern is to measure vibrational frequency in any molecule and especially specific functional groups present. Surface enhanced infrared spectroscopy (SEIRS) is an appreciable advancement of Infrared spectroscopy used to obtain the spectrum of absorption of a solid, liquid and gas. Its emergence facilitated the increase of speed and accuracy of the conventional technique by replacing the use of traditional prism and grating monochromators with an interferometer. It is used for the determination of variety of analytes in environmental and biological samples as its high sensitivity allows to detect the analyte at trace levels. Furthermore, it is commonly used for the characterization and monitoring of organic and some cases of inorganic pollutants on the basis of molecular structure and chemical bonding. Though various chromatographic, fluorimetric and phosphorimetric techniques have been traditionally used for such monitoring and characterizations, FTIR proves out to be an appealingly good alternative due to its remarkable characteristics such as little sample preparation, rapid analysis, better signal-to-noise (SNR) ratio and minimized use of hazardous solvents. This review aims to compile the miscellaneous features of SEIRS favouring its use as a sensing probe for the analysis of chemical species.

Keywords: Infrared Spectroscopy; SEIRS; sensing probe; chemical species; characterization.

* sgp_sinp@yahoo.com

Polymers are an important class of materials having different applications in various fields of science and technology, particularly in optics, electronics, biotechnology, photonics and space research. The study of changes in the properties of polymer material under the effect of ionizing radiation (electron and ion beam, x-ray and gamma radiation) has great importance due to its use in hard radiation environments such as particle accelerator, nuclear power plants, spacecrafts etc. Reaction mechanisms of product formation due to γ-irradiation (with total dose 570 kGy at a dose rate of 1.707 kGy/hr) in Polymethyl methacrylate (PMMA) have been studied by using Fourier transform infrared (FTIR), UV-Vis spectroscopic and x-ray diffraction (XRD) techniques. Gamma radiation is done at UGC-DAE CSR Kolkata centre, WB India. Results show that there are dose dependent changes like chemical and structural nature, formation of color centre, chain scission and cross-linking etc) observed in the polymer. Reaction mechanisms of product formation have been investigated.

OP-5

Synthesis and Characterization of 5-Methylisoxazole Derivatives by LCMASS & ^{1}H-NMR Technique and Its Potentials Application

Dr. Ajit Joshi
Department of Chemistry, Uka Tarsadia University, Maliba-Campus, Bardoli, Gujarat; a jit.joshi@utu.ac.in; ajitjoshi2k2@gmail.com;

The present disclosure of the invention presents a novel 5-methylisoxazole derivative & method of preparation thereof. These newly synthesized compounds were characterization and confirmation by LCMASS and 1H-NMR Spectroscopy. These 5-methylisoxazole derivatives showing antibacterial, antifungal and antimalarial activity, against the STD drugs. These compounds would be of better use in drug development to combat bacterial infections and as anti-malarial agents.

OP-6

Dual fluorometric detection of Cu2+ and Ni2+ ions via excimer quenching of quinoline moiety of quinoline-appended glucopyranose derivative

Mini Loya, Samiul Islam Hazarika and A. K. Atta*
Department of Basic & Applied Science, National Institute of Technology-Arunachal Pradesh, Yupia, Papumpare-791112, Arunachal Pradesh, India
miniloya22@gmail.com, akatta.chem@nitap.ac.in*

Among the various biologically important metals, copper is the third most plentiful element in living organisms and essential to many fundamental physiological processes [1]. On the other hand, Ni^{2+} is an important metal ion in biological processes and exists in the active sites of several enzymes and coenzymes for biosynthesis and metabolism of microorganisms and plants [2]. Both Cu^{2+} and Ni^{2+} ions are crucial trace elements in biological systems but they also act as significant environmental pollutants due to their inherent toxicity. In view of that, a simple triazole-linked quinoline-appended fluorescent sensor has been developed from inexpensive D- glucose in one synthetic step. The sugar-based quinoline-appended sensor exhibited excimer and monomer emissions in MeOH/H_2O (7/3, v/v) after excitation at 350 nm. We observed that the excimer emission of quinoline moiety at 481 nm was quenched with the increment of monomer emission at 391 nm in the presence of Cu^{2+} and Ni^{2+} ions in the aqueous methanolic solution [3]. The sensing ability of the sensor towards Cu^{2+} and Ni^{2+} ions was also established by absorption spectroscopy. Based on Job's plot experiment we found sensor exhibited 1:1 stoichiometric ratios for both ions which were further supported by mass spectra of the complexes. The limit of detection (LOD) values of the sensor for Cu^{2+} and Ni^{2+} were determined as 0.025 μM and 0.047 μM respectively. To the best of our knowledge, this is the first example of monoquinoline-based sensor which exhibited excimer quenching in the presence of Cu^{2+} and Ni^{2+} ions.

Keywords: Cu^{2+} and Ni^{2+} ions, quinoline, glucopyranose, excimer, fluorescence

Access & usability of Science kits for promotion of Laboratory skills among school students

Rashmi Sharma and L K Tiwary
RIE, Bhopal
rashminerie666@gmail.com

No science instruction is complete without laboratory work. Experimentation is part & parcel of all sciences.

At the same time, taking good care of our environment has become not only imperative in the present rapidly progressive society rather it is an urgent concern of every conscious being in the planet earth. Different branches of science, plays an important role for advancement of all walks of life. For an individual, the journey to become a chemical scientists starts at very early stage of schooling and ends till post-graduation of even after that. In order to practice certain required skills in science, every student is supposed to provide opportunities for development of some certain skills among students. There are numerous reasons they restricts the students to try their hands on practical work. Students are deprived of the laboratory experiments and in turn are unable to develop some certain skills those are very important in their lives. In order to fulfil the requirements related to laboratory facilities schools are provided support from various organisations including NCERT. NCERT not only develops the science kits, but provides the hands on experiences & training to the teachers to use these kits in the real class room situations.

In the present paper an attempt has been made to find out the status of access & usability of science kits in the schools of western states of India. It is found that all the schools do not have the access of the science kits in their schools. Some schools where these kits are available, are also not in position to make best use of these kits in the interest of the learners. The paper also attempts to analyse the reasons for neglecting the experimental work in Indian schools which otherwise is the back bone of all higher level experiments and researches in science

OP-8

Removal of phenol from wastewater using industrial wastes as adsorbents: A step towards circular economy

Ashanendu Mandal, Sudip Kumar Das
Chemical Engineering Department
University of Calcutta, 92 A. P. C. Road, Kolkata-700009, India
ashanendumandal@gmail.com

The wastewater containing phenol needs to be treated suitably as it is toxic. There are several techniques developed for this; however adsorption seems to be very effective due to its simplicity and low-cost. In this study three industrial wastes viz., rice husk ash, red mud and clarified sludge from basic oxygen furnace have been used as adsorbents. These waste materials usually do not have any economic value and are therefore discarded from their generating plants. Initially the adsorbent characterizations were performed by SEM, XRD, FTIR and BET analyzers. Thereafter the adsorbent potential of each adsorbent was examined at different process conditions i.e., initial phenol content, initial pH, adsorbent quantity, contact time and temperature. The maximum phenol removal percentage was found to be 95%, 87.5% and 63% for rice husk ash, red mud and clarified sludge respectively at optimum process condition. The experimental results were then verified for kinetic study using several models like pseudo-first order, pseudo-second order, Elovich, Reichenberg, Fick, Boyd and Furusawa-Smith models. The isotherm study was carried out using Langmuir, Freundlich, Temkin and Dubinin-Radushkevich models. The thermodynamic study was performed using the outcomes at different temperatures. The regeneration, safe disposal and scale-up design were deliberated for testing their commercial applications. Finally the innovative prediction analysis was conducted using MLR modeling. The adsorption experiments were also repeated with the real industrial wastewater collected from a coke-oven plant. The study established that these industrial wastes are effective for phenol removal from wastewater and can thus be considered as valuable contributors towards circular economy in the third world countries.

Keywords: Phenol, Wastewater, Adsorption, Industrial wastes, Rice husk ash, Red mud, Clarified sludge

Natural product is considerd as remedial resource for many diseases. Pterocarpus marsupium is very renowned tree which is known as its potential therapeutic applicability. Pterocarpus marsupium is also known as Indian kino tree because this is native to India. It is used to cure many diseases like elephantiasis, leprosy, leucoderma, diabetes, opthalmopathy, greyness of hair and asthma etc. Many chemical consituents from Pterocarpus marsupium have been isolated as- C glucoside, 1-(2', 6'-dihydroxyphenyl)-β-D-glucopyranoside, 7-Hydroxy-6, 8-dimethyl flavanone-7-O-alpha-L-arabinopyranoside and 7,8,4'- trihydroxy-3', 5'-dimethoxy flavanone-4'-O-beta-Dglucopyranoside etc. A new compound Apigenin 6-C-β-D-(2''-O-β-D-glucopyranosyl) has been isolated from the bark of Pterocarpus marsupium. The structure of new isolated compound has been confirmed with the help of MS, 13 C NMR, IR, UV, 1 H NMR, synthesis and Chemical degradation.

Novel strategy for optical chemical sensing of nerve agent simulants

Chandra kant Maurya, Uma Pathak and Pradeep Kumar Gupta*
Synthetic Chemistry Division, Defence Research & Development Establishment (DRDE) Gwalior (MP) 474002

The extreme toxicity, facile production, easy accessibility compare to conventional weapons, there is always possibilities to use of nerve agents by terrorist organization & military regimes which dictates the requirement to develop selective & sensitive detection system for them[1]. Various detection methods based on electrochemistry[2], ion mobility spectrometry[3], surface acoustic wave (SAW) devices[4], biosensors[5], etc were developed. However, these detection methods have at least one of the limitations like limited selectivity, poor sensitivity, operational complexity, low portability etc. As an alternative, optical chemical sensors including chromogenic and fluorogenic sensors have gained great importance as they are portable, cheap and enable neked eye detection of analyte. However, reported chromogenic and fluorogenic detection methods for CW agents and their simulants suffer from poor selectivity due to the involvement of single non-specific nucleophilic-electrophilic interaction between chemical sensor molecule and analyte as similar interaction with non- toxic molecules can give rise to false positive alarms. We, herein, describe a novel strategy for selective detection of nerve agent simulants which involves sequential interactions between the sensing system and analyte's reactive sub units. These multiple interactions modulate the overall optical properties of the sensing system which is specific to the nerve agent simulants. This novel strategy was found to be selective for the detection of nerve agent simulants and did not give response in presence of other common interferences including phosphorus derivatives, acid and anions.

Fluorescent Carbon Quantum Dots as Sensing Probe for Selective and Sensitive Detection of Hg^{2+} in Water Samples

Lavkesh Kumar Singh Tanwar, Srishti Sharma and Kallol K. Ghosh*
School of Studies in Chemistry Pt. Ravishankar Shukla University, Raipur 492010 (C.G.)
Email- singh1708lavkesh@gmail.com

Carbon quantum dots (CQDs) are promising fluorescent sensing probe for applications in metal ion detection, biosensing and bioimagining. Herein, we have synthesized carbon quantum dots (CQDs) by simple microwave assisted technique for Hg^{2+} detection in water samples via.fluorescence quenching and FT-IR spectroscopic approach. The morphology and chemical structure of synthesized CQDs was characterized by TEM, FT-IR, ^{13}C-NMR, fluorescence and UV-vis spectroscopic technique. The resultant CQDs bears spherical morphology with an average size of 2-4 nm. The binding parameters, as Stern-Volmer quenching constant (K_{sv}) and binding constant (K_a) for CQDs-Hg^{2+} system was investigated by fluorescence method, whereas UV-vis techniques was employed for determination of thermodynamic parameters, as Gibb's free energy (ΔG), enthalpy (ΔH) and entropy (ΔS) at three different temperature (295, 298 and 305 K). Moreover, selectivity assay for Hg^{2+} detection has been studied in presence of other metal ions by FT-IR as well as fluorescence spectroscopy. Analytical assay was also successfully applied for Hg^{2+} in spiked water samples collected from different areas of Chhattisgarh.

Keywords: Carbon quantum dots; FT-IR; fluorescence; UV-vis; mercury; chemical sensor.

Comparative Study ofPalladium(II) Extraction Using EBIMTT and DMABIMTTExtractants

Uzma Parveen Shaikh*[1], Mohammad Mohsin[1]
[1]Dr. Rafiq Zakaria College for Woman (Navkhanda), Aurangabad M.S. India
* upshaikh@gmail.com

Comparative study of extraction of Palladium (II) was carried out using two different sulphur containing extractants namely EBIMTT (4-(4-ethylbenzylideneimino)-5-methyl-4H-1,2,4-triazole-3-thiol,Extractant 1) and DMABIMTT (4-(4-dimethylaminobenzylideneimino)-5-methyl-4H-1, 2, 4-triazole-3-thiol, Extractant 2) in a Chloroform diluent. Also various parameters such as shaking time, diluent used, concentration of extractants, and concentration of HCl were studied. Extractant 1 could also be used for extraction of Pd ion but extractant 2 was found more efficient than extractant 1 for Pd (II) recovery. In addition Pd(II) was stripped from organic phase, thus enabling the reuse of extractants.

Selective production of aromatic compound from the waste plastics by using porous carbonaceous material as catalyst

Samyabrata Bhattacharjee[1], Dr. Sunil baran.Kuila[2*]
[1,2]*Department of Chemical Engineering, Haldia Institute of Technology, Haldia 721657, West Bengal, India*
Corresponding Author name: Dr. Sunil baran Kuila, sunilbarankuila@gmail.com,

The global production of plastics is increasing rapidly because of their vital role in today's daily activities. Plastics are widely used because of its advantages such as cheapness, endurance, lightness, hygiene and design adaptability. The sharp rise and mass consumption of plastics produce a great quantity of wastes, which poses a formidable challenge for waste management. Domestic waste generally contain many kind of waste plastics, including polyethylene, polypropylene and polyvinyl chloride,which is 70% of total was tea sper L l etal. 2001. Approximately 10-20 million tons of plastics end up in the oceans each year as per Tranksali et al. Thus, it is becoming increasingly challenging to manage and control the use of plastics due to their adverse environmental effects. The landfill deposition of municipal waste plastics (MWP) may cause environmental problems and is becoming more expensive. Due to increasing volume of MWP and decreasing landfill capacity for disposal, landfill becomes more challenging. In addition, landfill can release hazardous sub-stances and plastic wastes take long time to degrade. In this paper we focus on the production of clean fuel from waste plastics by catalytic pyrolysis. Catalytic pyrolysis is a novel high efficient technology on recycling of waste plastic and it is environment friendly also. It can also stabilize global need of fossil fuel which tends to be crisis. Pyrolysis of different waste plastics such as polyethylene, polypropylene, polystyrene and polyvinyl chloride was achieved at abenchscale to produce clean fuel of required calorific values or chemical feedstock. Combination of pyrolysis with catalytic up gradation process can prove significant economic and economical option in conversion of e-waste plastic. Herein, we conducted the pyrolysis by utilizing the porous waste carbonaceous material as catalyst. Study the effect of catalytic temperature, residence time and plastic waste component on the production of Aromatic compound. The entire process is undertaken in closed reactor vessel followed by condensation, if required. Waste plastics while heating up to 500 to 900 ^{o} C convert into liquid-vapour state, which is collected in condensation chamber in the form of liquid fuel. Further optimize by soft computing techniques.

Keywords: Waste plastics; Aromatic production; Catalytic thermochemical conversion

Porous Organic Molecules to Porous Organic Polymers: Potential Catalysts for CO_2 Fixation

Arkaprabha Giri, MD. Waseem Hussain, and Abhijit Patra*
Dept. of Chemistry, Indian Institute of Science Education and Research Bhopal, Bhopal, MP, India
E-mail: arkaprabha16@iiserb.ac.in,abhijit@iiserb.ac.in

All-organic nanoporous materials, e.g., organic cages, porous organic polymers (POPs), have attracted significant attention in the last few years for their potential applications in catalysis owing to the functional tunability, high porosity, and outstanding hydrothermal stability.[1] Catalytic fixation of CO_2 with epoxide for the synthesis of cyclic carbonates has drawn a great deal of interest because it provides a viable route to minimize the production cost of various materials derived from cyclic carbonates using easily available, renewable raw material, CO_2, as one-carbon building block.[2] The high atom economy, as well as the versatile utility of the cyclic organic carbonates, make the conversion of CO_2 to cyclic carbonates an industrially relevant reaction.[2]Our group has focused on the importance of the 'nanoconfinement' effect in the aforementioned catalytic process.[3] In this presentation, I shall discuss the

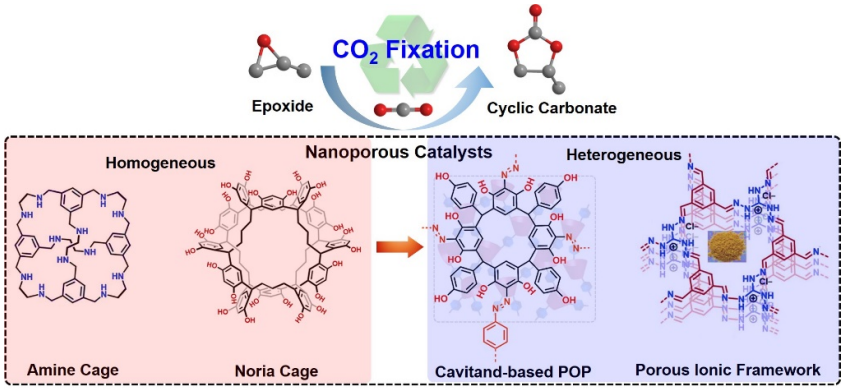

Figure: Pictorial representation depicting the nanoporouscatalysts from cage to frameworks for catalytic fixation of $CO_2$to cyclic carbonates.

nanoporous organic amine cage, and noria as homogeneous catalytic platform for CO_2 fixation.[4a] Addressing the recyclability issue, I will switch to the heterogeneous catalytic platform discussing the use of recently developed cavitand-based POPs,[4b,4c] and N-rich triaminoguanidinium-based ionic frameworks for the efficient CO_2 fixation into cyclic organic carbonates.[4d]

Fabrication of Gold Nano-Ink as Electrochemical Sensor for Glucose Detection

Tushar Kant and Kamlesh Shrivas*
School of Studies in Chemistry, Pt. RavishankarShukla University, Raipur-492010(CG)
Email Id: tusharkant40@gmail.com

To the best of our knowledge, the inkjet-printed paper electrode (PPE) with gold nanoparticles (AuNPs)-ink as a non-enzymatic electrochemical sensor for detection glucosein blood samples is reported for the first time. In this work, a green method is used for the synthesis of aqueous AuNPs-ink and has been fabricated on the paper substrate using office desktop inkjet-printer.PPE with AuNPs is sintered at 100º C for 30 min to obtain a conductive film. The prepared AuNPs-PPE is employed as a working electrode in cyclic voltammetry (CV) for the sensitive measurementof glucose in blood samples. The fabricated AuNPs-PPE demonstrated an excellent electrochemical activity and rapid electron transfer kinetics towards the oxidation of glucose. A wide linear range, 0.05-35 mM with a limit of detection, 10 µM is observed for the determination of glucose. The advantages of using AuNPs-PPE in the electrochemical measurements are flexible, user-friendly, biodegradable, economic and enzyme-free with respect to the commercially available electrochemical sensors.

Keywords: AuNPs, electrochemical sensor, glucose, bloodsamples.

Single and mixed micelle as catalyst in promoted organic transformation

Animesh Acharjee[1], Bidyut Saha[2]
Department of Chemistry, The University Burdwan
[1]anisuk999@gmail.com, 7384757214
[2]bsaha@chem.buruniv.ac.in, 9476341691

Growing concern for environmental issues has compelled synthetic organic chemists to adopt sustainable way towards green synthesis [1]. Catalytic organic transformation in aqueous medium is indeed a green modification in the field of synthetic organic chemistry [2]. To perform organic reaction in water micelle plays a dominating role by solubilising nonpolar organic compound in water and catalysing a chemical transformation [3]. Presently different types of organic reactions are regenerated in micellar medium [4-7]. Here oxidation of aliphatic alcohol is presented. Oxidation dynamics of alcohol oxidation was achieved by aqueous chromic acid under pseudo 1st order condition. The reaction was catalysed by single micelle and mixed anionic-nonionic micelle. Mixed micelles are of low cost and found to be beneficial for industry. Further use of heteroaromatic bases enhanced the rate of reaction. Combined effect of micelle and promoter completes the reaction almost instantly. The product of reaction was characterized by different spectroscopic methods. Formation of mixed micelle and encapsulation of alcohol in micellar core is established by NMR study [2].

Skin cancers are often resistant to conventional chemotherapy. Nanomedicine plays an important role in developing alternative and more effective treatment strategies for cancer theranostics. In this present study, we focused on the Green synthesis of metallic nanoparticles, which is a cost-effective environment-friendly technique. *Plumbago zeylanica L.* has ethnomedicinal values. With this background in this study, the plant extract of *Plumbago zeylanica L.* was used to fabricate silver nanoparticles. The biophysical analysis revealed the formation of spherical nanoparticles with a diameter of less than 30 nm affirmed by SEM analysis. The FTIR results prove that the biological components present in the *Plumbago zeylanica L.* had reduced the silver ions to synthesis silver nanoparticles. Significant cytotoxic potentials of the nanoformulation were determined by MTT assay on B16 melanoma cells. There is a significant reduction in several viable melanoma cells were observed in AgNPs treated cells compared to the control cells. The reduction of viable melanoma cells was in a dose-dependent manner. Our results authentically prove the biosynthesized AgNPs induces apoptosis in melanoma cells and it possesses the anticancer property.

Product selectivity in aqueous phase phenol hydrogenation on well-defined supported Pd nanostructures (spheres, cubes, and octahedra) was studied using defined experiments and density functional theory (DFT) simulations. On Pd spheres and octahedra, the reaction initially showed high selectivity (in the first 3 h, at 363 K and 5 bar H_2 pressure) toward the partially hydrogenated product cyclohexanone. On prolonged operation (>20 h of reaction time), a shift in the product selectivity (up to 100%) toward the completely hydrogenated product cyclohexanol was observed on Pd spheres and octahedra. In contrast, the reaction on Pd cubes, which only had {100} facets, showed a high selectivity (~90%) toward the product cyclohexanone even after 40 h, at the same reaction conditions. Since the {111} facets are expected to be the majority sites on a spherical particle, we attribute the selectivity trend observed on spherical Pd particles to be primarily controlled by the selectivity trend on the Pd{111} facets. This observation was further confirmed on performing the hydrogenation reaction on a mixture of Pd cube and Pd octahedron particles in a ratio of 25:75 (representing the site ratio of a spherical particle). DFT simulations provided a mechanistic insight into the reactivity of the two different facets ({100} and {111}) toward phenol hydrogenation. The calculations revealed that the selectivity significantly depended on the activation barriers involved in cyclohexanone hydrogenation on the Pd{111} facets (77 and 57 kJ/mol) as compared to those on the Pd{100} facets (97 and 101 kJ/mol).

Development of Fly Ash Based Geopolymer Concrete Using Nano-Silica

Sameer Vyas[1], Mohmmad Sameer[2]
[1]- Central Soil and Materials Research Station, New Delhi, India.
[2]- Gautam Buddha University, Greater Noida, India.
samyog78@yahoo.com.

With the growing infrastructure development all around the world demand of Portland cement are increases day by day. The huge production of cement is associated with releases of CO_2 causing global warming issues. Therefore several efforts are in progress to reduce the use of Portland cement in concrete. These include the utilization of supplementary cementing materials such as Fly ash, Silica fume, Ground granulated blast furnace slag, Rice-husk ash and Metakaolin etc.

The concept of sustainability of structures is touching new heights and many green building materials are tried and tested as partial or complete replacement for the cement. In this respect, the geo-polymer technology shows considerable prospect for application in concrete industry as an alternative binder to the Portland cement. Development of geo-polymer concrete using class F fly ash brings many advantages like; enhancing workability, durability, better strength as well as lowering the price.

Nowadays, Nano Technology is also gaining prominence in the field of construction industries. In this study an attempt is made to find the effect for addition of Nano silica in geo-polymer concrete .The geoploymer concrete cubes were prepared using different percentage of nano silica. Experimental procedures are presented in Fig. 1,2 & 3. Respectively.

Figure-1. Casting of Concrete Cubes

Figure-2. Curing of Concrete Cubes

Figure-3. Compressive Strength of Concrete Cubes

After finalizing the mixed design, the compressive strength were determined. The experimental study will also be carried out for durability aspects under different aggressive environment. The results obtained so far shows that geo-polymer concrete with nano silica addition exhibit good strength. The beneficial effects

of nano silica in improving the workability, microstructure and strength qualities have also been established experimentally. The results so far obtained for compressive strength are presented in fig.4.

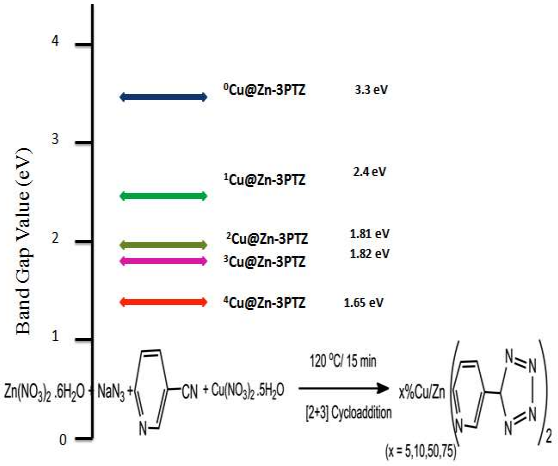
Band gap engineering of Cu@Zn-3PTZ Metal–organic framework composites

Arti Chouhan *, Ashutosh Pandey
Department of Chemistry, MNNIT Allahabad, Prayagraj, India
*artichouhan@mnnit.ac.in

Visible light-induced photocatalysis is a potential method due to the proficient use of solar energy for environmental remediation. Investigations on metal-organic framework (MOF) compounds have attracted the researchers due to large surface area of MOF, well-ordered porous structure, and tuneable architecture with a tailorable competence to absorb light. In this paper, synthesis of Zn (II) and 3-pyridyltetrazolate based MOFs using microwave assisted hydrothermal process has been discussed. Synthesized MOF was used as host-matrix for in-situ loading of Cu^{2+} ion, and subsequently copper loaded luminescent composites were finally synthesized. FTIR, XRD, SEM, TGA, CHN analysis were carried out to confirm the structure, crystallinity, stability, and elemental composition of MOFs. With different input concentrations (5%, 10%, 50%, 75%) of doped Cu ions, the band gap of Zn-3PTZ {PTZ =5-(pyridyl) tetrazolate} (3.3 eV) can be reduced to 1.65 eV, which can be directly excited by visible light. From the analysis of the results, it can be concluded that these materials have huge photocatalytic activity, stability and exceptional recyclability for techno-economically viable applications in the field of sustainable energy.



OP-3

A thermodynamic analysis on liquid-crystal phase transition in supercooled SW-Silicon

Arvind K. Gautam
National Institute of Technology Hamirpur, (H.P.), 177005, India
akgautam@nith.ac.in

The silicon is mostly exist in the liquid, amorphous and crystal state. The cyrstal and amorhphous silicon are extensively used in the electronic chips and solar cells industries. Interestingly, the amorphous form of the silicon (hereafter referred to as low density amorphous phase or LDA phase) is not a glass, i.e., it does not represent a frozen state of silicon melt (which we will refere to as high density liquid phase or HDL phase). This is evident from the fact that there are important differences between the HDL and the LDA phases. Since the interfacial energy (γ) plays an important role in the dynamics of such phase transition because of high activation energy according to the homogeneous nucleation theory. Therefore, to understand the phase behavior in real silicon, we have studied the liquid-crystal interfacial free energy (γlc) of silicon at the transition point by using cleaving wall method. This is a unique method to compute the interfacial free energy acurately at or near the transition temperature. In this work, we have performed NVT-MC simulation technique in the interfacial free energy calculations to understand the thermodynamics of liquid-crystal transition of silicon modeled by an empirical potential known as the Stillinger-Weber (SW) potentials.

In recent years, where in daily life pesticides play a critical role, also water pollution and pesticide residues in the food chain have become a serious environmental and health hazard problem. Excessive use of such chemicals is a higher risk for plants, animals and humans which have from time to time been studied. Apart from the biological degradation, an effective technology is essential for complete mineralization of pesticides to non-toxic forms. In this short review paper discuss the removal depends on different factors such as a solution pH, catalyst charge, initial pesticide concentration, catalyst support or suspended catalyst, light strength.. This review is also summarizing the existing studies used for the degradation of pesticides; the need to mitigate the contamination issues associated with pesticides is seemingly the photochemical technology.

Understanding The Properties Of Different Types Of Chitosan And Their Value Addition

Neha Ghosh[1,2],Paresh L. Dhepe[1,2]*
[1]Catalysis & Inorganic Chemistry Division, CSIR-National Chemical Laboratory, Dr. HomiBhabha Road, Pune 411008, India;
[2] Academy of Scientific and Innovative Research (AcSIR), New Delhi 110025, India.
*E-mail addresses: n.ghosh@ncl.res.in; pl.dhepe@ncl.res.in

Chitosan is derived from chitin which is the 2nd most plentiful bio-polymer on earth after cellulose.In view of this, it is very important to develop an efficient and environmentally benign method to valorize chitosan.In past few decades, researchers have put efforts for the conversion of lignocellulosic biomass but very less attention has been paid on valorization of animal biomass. In the literature, mineral acids and bases, supported metal catalysts under very high hydrogen pressure, high temperature is used for the conversion of chitosan and chitin. These methods have several drawbacks such as corrosion, difficulty in catalyst separation, recyclability etc. In this study, we have done detailed characterization of seven different chitosan using IR, ^{13}C NMR, XRD, TG-DTA, SEM, CHNS elemental analysis, ICP-OES analysis, Viscosity measurement to understand the physical and chemical properties. It is found that viscosity, molecular weight, morphology etc. are different in same type of sample from different company. Solid acid catalyzed valorization of chitosan to value added chemicals is done in this study. Hydrothermally stable catalysts are synthesized to study their effect on chitosan depolymerization. Effect of different solid acid catalysts are studied under inert atmosphere and comparatively low temperature. HPLC and LC-MS analysis confirms that chitosan is getting converted during reaction to form different products.

Removal of Brilliant Green Dye from Aqueous Solution using Sludge Produced from Common Effluence Treatment Plant

Vibha Malviya[1]*, M.K. Dwivedi[1]
[1]* Department of Chemistry, Govt. Holkar (Model, Autonomous) Science College, Indore (MP) 452001
id.vibha220391@gmail.com

Dyes are color organic compounds which are discharge in sewage water from many industries such as leather, fabric, textile, paper, printing and cosmetics. Annually, a huge amount of dyes and pigments (over 7X105 tons) are being produced throughout the world and 90% of this production in used in textile industry. In the present study, Sludge (CETP) was employed to develop an effective adsorbent for the removal of brilliant green dye from wastewater. The characteristics of sludge were studied viaby XRF, SEM, XRD and FTIR. Batch studies were carried out to study the effect of pH, adsorbent doses, adsorbate concentration, and temperature and contact time. The results of batch studies revealed that the adsorption of brilliant green was strongly pH dependent and the maximum removal efficiency was found 95% with initiated dye concentrationat equilibrium pH of 5.0. Optimum adsorbent dose and contact time were found to be 15 g/l within4 hours respectively. Kinetic studies have been being performed to have an idea of the mechanistic aspects of the process. The result also shows that adsorption increases with increase in temperature thereby showing the process endothermic in nature. Adsorption data have also been correlated with both Langmuir and Freundlich isotherm models. Thermodynamic parameters were also determined.

Keywords: Brilliant green dye, sludge(CETP), Adsorption, Isotherm models and kinetics.

Physico-chemical and Toxic Heavy Metal Analysis of Groundwater aroundLancoAmarkantak Power Plant Areas in Korba District, Chhattisgarh, India

Krishna Kumar Kashyap and Manoj Kumar Ghosh
Department of Chemistry, Kalinga University, Nava Raipur
krishna28kalingauniversity@gmail.com

Recently on increasing the contamination of aquatic environment by domestic sewage and industrial effluents has focused attention on the behaviour and interaction of many rare and neglected elements in the biosphere. Bioaccumulation of heavy metals in living organisms occurs due to their property of persistence and non-degradability of the complex organic compounds. This paper studied the physico-chemical properties and toxic heavy metals in groundwater. The present study focuses on the characteristics of ground water samples collected from around LancoAmarkantak Power Plant Areas in the Korba District during the premonsoon, monsoon and postmonsoon seasons of 2019-20. A total of 16 groundwater samples were analyzed for important parameters of physico-chemical and toxic heavy metals. Comparing the findings against drinking water quality requirements set by Indian standards for maximum acceptable level of drinking water quality (BIS), ICMR, USEPA, and WHO; some samples were found not to be portable for human consumption.

Keywords:- Groundwater, Contamination, Heavy metal, Power plant, Drinking water

L-cysteine Functionalized Silver Nanoparticles For Selective and Sensitive Colorimetric Detection of Vitamin B1 in Food and Environmental Water Samples

Beeta Rani Khalkho* and Manas Kanti Deb
School of Studies in Chemistry, Pt. Ravishankar Shukla University, Raipur-492010, Chhattisgarh, India
bittu1ranibeeta@gmail.com

Here, we report the use of L-cysteine modified silver nanoparticles (Cys-capped AgNPs) as a colorimetric probe for determination of vitamin B1 (thiamine). This method is based on the measurement of red shift of localized surface plasmon resonance (LSPR) band of Cys-capped AgNPs in the region of 200-800 nm. The color of Cys-capped AgNPs was changed from yellow to colorless by the addition of vitamin B1. The mechanism for detection of vitamin B1 is based on the electrostatic interaction between positively charged vitamin B1, which causes the red shift of LSPR band from 390 nm to 580 nm. The interaction between Cys-capped AgNPs and vitamin B1 was theoretically explored by density function theory (DFT) using LANL2DZ basis sets with help of Gaussian 09 (C.01) program. The morphology, size distribution and optical properties of Cys-capped AgNPs were characterized by transmission electron microscope (TEM), UV-Visible spectrophotometry, Fourier transform infrared spectroscopy (FTIR) and dynamic light scattering (DLS) techniques. The method is linear in the range of 25-500 µg mL^{-1} with correlation coefficient (R^2) 0.992 and limit of detection of 7.0 µg mL^{-1}. The advantages of using Cys-capped AgNPs as a chemical sensor in colorimetry assay are being simple, low cost and selective for detection of vitamin B1 from food (peas, grapes and tomato) and environmental (river, sewage and pond) water samples.

Carbon Dioxide Adsorption And Its Chemical Fixation By Chitosan -Graphene Oxide And Arginine Based Composites

* nzsiddiqui90@gmail.com

Carbon dioxide (CO_2) gas is the main greenhouse gas in the atmosphere which is primarily responsible for global warming and climate change. The most pressing challenge is contemporary environmental research is to reduce and control the amount of anthropogenic CO_2 gas inthe atmosphere by developing an effective and efficient materials and methods. Herein we have introduced composites materials of chitosan with graphene oxide and arginine and which was characterized by fourier transformation infrared spectroscopy (FTIR), X-ray diffraction (XRD) and scanning electron microscope (SEM) techniques. In FTIR spectrum, characteristic peaks around 3100-3300 $cm^{-1}$and 1740 cm^{-1} almost vanishes in resulting compounds indicates successful grafting of graphene oxide and arginine in CS matrix, XRD peaks shows crystal structure turns into amorphous nature and SEM analysis indicates the porous structure of resulting compounds in comparison to starting materials. This chitosan composite was used for the CO_2 adsorption and the adsorptioncapacity of CO_2 gas was measured by TGA method on its solid surface. The CO_2 gas adsorption was found to be 240 mg/g (5.45 $mmolg^{-1}$) at 35°C, hold for 35 min. Thiscomposite show much higher CO_2 capture capacity than thepure chitosan.The conversion of CO_2 gas into valuable organic molecules is underway in our laboratory. Thus, we believe that this study will help toreduce the anthropogenic CO2 gas from the atmosphere.

Keywords: Chitosan, Grpahene oxide, Arginine, Carbon dioxide, Adsorption, Conversion.

suvanicuj@gmail.com

Bacterial infections being sporadic and uncontrollable it demands an urgent paradigm shift in the development of novel antibacterial agents. This work involves the fabrication of Cu_2O nanopetals over copper foil that shows superlative antibacterial and superhydrophobic properties. A superhydrophobic surface has been fabricated using the electrochemical deposition (ECD) method. Here, it is aimed to establish the superior antibacterial activity as an outcome of the inherent superhydrophobic property of the as-fabricated nanostructures. The present study finds that the elevated value of water contact angle (154±0.6) does not allow proper bacterial adhesion, and it is impugn from the possibility of biofouling. Specifically, two kinds of bacterial strains have been tested and the time response of the antibacterial activity has been studied over a period of 12 hours, taking DH5α *E. coli* as a gram-negative model and *B. subtilis* as a gram-positive model. Higher antibacterial effects were observed for gram negative model (*E. coli*) owing to its simplistic cell wall structure which facilitates the easy diffusion of Cu^{+1} ions into the bacterial membrane. The simplicity of the developed method of fabrication along with the supercilious superhydrophobic nature and excellent antibacterial property of the material, owing to its synergistic biophysical and biochemical modes of biocidal action, establishes its viability in tons of applications.

Room Temperature Self-healable and Mechanically Robust Polymeric Materials for Sustainable Society

Dr. Anil Kumar Padhan and Dr. Debaprasad Mandal*
Department of Chemistry, Indian Institute of Technology Ropar, Punjab-140001, India
anil.padhan@iitrpr.ac.in, dmandal@iitrpr.ac.in

Polymeric materials are used in nearly all areas, from daily life-to-constructions of human body parts. However, these polymeric materials may have possibilities of damages during the course of use and are therefore required to replace with similar materials. Introduction of polymeric materials, which have ability to repair itself from the damages or cracks referred as self-healing materials, will be useful to enhance the safety index, long-term durability, minimizing the system breakdown and allows us to reuse. One of the most significant feature of living organisms is their self-healing ability after suffering from the damage; for example, self-recovery of our damaged skin, autonomous healing of the bone fracture, etc. Mimicking the self-healing features from nature, synthetic polymeric materials are highly demanding for sustainable self-life and prevention of cracks at the micro-level. The utilization of self-healing in a specific polymeric system for a particular application such as aeronautics, aerospace, self-stratifying coating, flexible electronics or battery, films, paints, soft robotics or xenobiotic, 3D/4D printing, neural prostheses, implantable biosensors, structural similarity towards the biological tissues, artificial skin is the key concern. This work presents an ionically crosslinked, mechanically robust, efficient, and multiple times self-healing polymeric hydrogel involving polymeric cationic and polyanion having a dual interpenetrating network of hydrogen bonding and ionic interactions. Fine-tuning of polymeric cation and anion allows achieving tailormade hydrogel exceptional mechanical properties such as very high tensile strength (30 MPa), a superior toughness (43 MJ/m^3) and high fracture energy (4300 J/m^2) and ultra-stretchable (5400%). These hydrogels show rapid and repeated self-healing instantly, without any external stimuli providing ~90% of healing efficiency at room temperature. Additionally, the hydrogel exhibits transparency, flexibility, fire resistance and shows good conductivity. This new generation of self-healing polymeric materials having emerging physical, thermal, mechanical, electrochemical properties may further open the doors to exciting domains towards a sustainable society.

A Novel Agro Waste (*ArtocarpusHeterophyllus*) Adsorbent For Pb(II) Ions Sequestration From Wastewater

Ritu Gupta[1*] and Chhagan Lal Gehlot[2]
Analytical Research Laboratory, Department of Chemistry, School of Basic & Applied Sciences, Harcourt Butler Technical University, Kanpur, U.P., India- 208002
its.ritugupta25@gmail.com/c.lal9940@gmail.com

There is a demand to develop more effective agricultural agro-waste adsorbents to remove heavy metal ions from various aqueous media. the main target of the present research was focused on the selection of novel agricultural waste material. For this Purpose, Jackfruits leaves (*Artocarpusheterophyllus*) was chosen as a suitable adsorbent material for Pb (II) ion removal from synthetic or wastewater. Jackfruit leaves were naturally occurring and cost-effective agro waste material. To enhance the adsorption performance of Pb (II) ion on JFLP adsorbent, surface modification is preferred by using suitable reagents. Batch Adsorption experiments were carried out to investigate the varying parameters like initial Pb (II) ion concentration (12.5-100) ppm, pH (2-6), and exposure time (180) on Pb (II) adsorption and also studied the effect of Adsorbent dosages on Pb (II) adsorption. The chemically modified adsorbents were also pointed out by its morphological and characterization techniques using Fourier transform infrared spectroscopy (FT-IR), FESEM with EDX, FTIR, N_2 adsorption-desorption and surface area analysis by BET method and also the pore size and pore volume study by BJH method.

The aim of the present work is to investigate the compatible adsorption behavior and identify the adsorption capacity of the all chemically modified adsorbents.

Keywords: Adsorption, agro waste adsorbents, chemical modification, adsorption capacity, Pb(II).

Environment friendly flexible paper-based electrodes towards electrochemical biosensing application

Neha Thakur, Debaprasad Mandal, Tharamani C. Nagaiah
Department of chemistry, IIT Ropar Rupnagar Punjab-140001, India
email:2017cyz0005@iitrpr.ac.in,contact no.9459829342

The advancement in research mainly covers cost reduction, waste management, and the well-being of a human. In this context, rapid diagnosis of diseases at their initial stage is life-threatening for the medical industry and is especially meaningful for disease diagnosis in promoting general public health and regulating physiological activity.[1] However, an abnormal level of biomolecules causes several disorders. Over decades, numerous devices have been developed for detecting biomolecules; amongst these techniques, electrochemical sensors have gained a dominating role in clinical diagnostics due to advantages such as rapid response, simplicity, high sensitivity, and low cost. Nodaway's, considering the inexpensive, portable, easily disposable, lightweight, reduction of waste materials, more attention is given towards the design of a flexible sensor for a wide range of applications as they are adaptable for modification with a variety of functional groups for performing biomolecule detection.[2] Also, considerable improvements have been made in developing efficient electrochemical material for biosensing applications. Herein, we have designed environment-friendly paper-based flexible material for electrochemical biosensing of biomolecules, mainly dopamine, cholesterol, and glucose.[3] Additionally, due to the existence of specific biomolecules in human blood serum, real-time analysis hasbeen performed as the confirmation of a related disease.

Designing electrolytes for next-generation, safe and energy-dense lithium metal based batteries

Tino S Thomas and Dr. Debaprasad Mandal*
Department of Chemistry, Indian Institute of Technology Ropar, Punjab-140001, India
tino.19cyz0025@iitrpr.ac.in, dmandal@iitrpr.ac.in

Ever growing demand for fossil fuels and limited availability along with environmental problems associated with it has motivated researchers to look for alternative and environmental friendly high performance energy conversion and storage systems. In this regard, lithium-ion batteries (LIBs) have gained significant attention owing to its unmatchable combination of high power and energy density along with low self-discharge rate which makes it an ideal candidate for portable energy devices.[1] However, LIBs suffer from low charge capacity and usage of high energy electrodes are restrained due to low-flash point of conventional electrolytes which limits its high energy output. Ionic liquids (ILs) are a promising candidate to solve the problems of flammability, low-flash point and aid in achieving high energy output owing to their tunable properties, high thermal and electrochemical stability as well as non-flammability. Imidazolium based ILs have gained popularity due to their favorable melting point, moisture and temperature stability and ease of tenability. Imparting functionalities to IL in order to minimize their viscosity can enhance its ionic conductivity. Herein, we present imidazolium based ILs bearing ether-ether and ether-siloxane functionalities over both sides of imidazolium ring to control their thermo physical properties.[2]

Keywords: Lithium-ion batteries, ionic liquids, imidazolium.

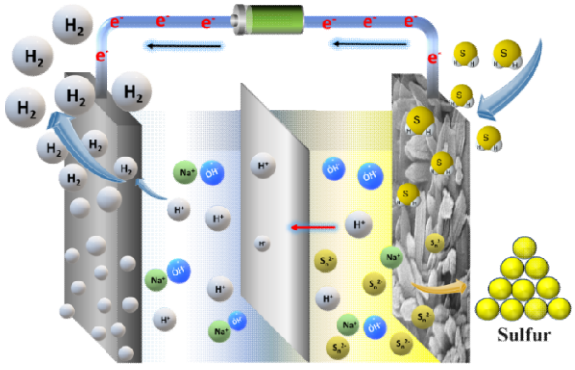
"H_2S" from environment pollutant to new form of energy

Mukesh Kumar, Tharamani C. Nagaiah
Department of chemistry, IIT Ropar Rupnagar Punjab-140001, India
2017cyz0004@iitrpr.ac.in,contact no.9805303075

Highly efficient and cost-effective production of hydrogen (H_2) promises to play a vital role in green energy production due to its high energy density, low-pollution,and renewable nature. The electrocatalytic decomposition of H_2O to H_2 and O_2 considered to be a most sustainable method for pure H_2 production, unfortunately it stumble due to potentially uphill and energy-consuming sluggish anodic evolution reaction (OER).[1] Contrary to H_2O isostructural hydrogen sulfide (H_2S) possesses lower bond dissociation energy. Therefore, anodic sulfide oxidation reaction (SOR) will be more energy-efficient than OER. Presently, the Claus process is the most popular industrial technology for removing H_2S, but energy wasted in the form of steam.Therefore, electrochemical conversion of environment pollutant H_2S into H_2 and Sprovide a way to remove pollutant H_2S and also emerges as new energy source.[2] However, the industrialization of such energy-efficient technology never meets the expectation in reality in the absence of cost-effectiveand robustelectrocatalyst. Herein we have designed $CoFeS_2$ based catalyst that exhibited lower onset potential of 0.2 V *vs.* RHE towards SOR, which is 1.27 V lower than OER. Notably, only a 1.2 V commercial battery easily derives H_2S electrolysis, which is impossible for H_2O splitting demonstrating the tremendous future prospective of H_2S for cheaper hydrogen production for a sustainable economy.



Scheme 1. Schematic representation of H_2S electrolysis into cathodic H_2 and anodic S by $CoFeS_2$.

AO-11

Mesoporous iron gallatenanocomplex for adsorption and degradation oforganic dyes

Anita Yadav, Rakesh Kumar Sharma*
Department of Chemistry, University of Delhi, India
aniganiwal18@gmail.com

The stability and porous nature of a nanocomplex are of importance for the practical utility like in adsorption orcatalytic activities. Mesoporous Iron gallate (Fe-Ga) nanocomplex was fabricated by means of effective, simple, convenient and rapid solvothermal method. These nanocomplexes were then utilized as a catalyst for rapid degradation of cationic (Toluidine Blue (TB)) and anionic (Rose Bengal (RB)) dyes without employing any auxiliary oxidants like Hydrogen Peroxide (H_2O_2), Sodium Borohydride ($NaBH_4$) etc. Analysis of the nanocomplex using various techniques like Powder XRD, N_2 (Nitrogen) adsorption/desorption, UV–vis spectroscopy and electron microscopy revealed mesoporous (pore size = 2.72 nm) structure with high surface area of 90.48 m^2 g^{-1}, uniform sizes of around 15–20 nm and outstanding adsorption and degradation properties. The nanocomplex adsorbed, decolorized and decomposed both the dyes within 10 min. Due to the negative zeta potential (14.6 ± 3.5) the particles preferably adsorb and degrade cationic dye (TB) because of the presence of positively charged amine groups. Furthermore, the catalyst is stable and reusable. Such material releases reactive oxygen species (ROS) such as hydroxyl radicals and primarily responsible for the degradation of dyes at enhanced rate. Such advancement can be extended to othernanocomplexes to efficiently enhance their catalytic activities and hence may be envisaged as a method for removal of dyes for detoxification of waste water.

Importance of measurement of CO impurity in high purity nitrogen at high- and lowcylinder pressureby Cavity Ring Down Spectroscopy Technique

Poonam Kumari[1,2], Gazal[1,2], Komal[1,2], Prabha Johri[1,2*], Daya Soni[1,2], S. G. Aggarwal[1,2] and Khem Singh[2]

[1]Academy of Scientific & Innovative Research (AcSIR), CSIR- National Physical Laboratory campus, New Delhi – 110012, India

[2]Environmental Sciences & Biomedical Metrology Division, CSIR- National Physical Laboratory, New Delhi – 110012, India

(*pjohri@nplindia.org)

Carbon Monoxide (CO), is often called the "Silent Killer" because of its ability to take lives quickly and quietly. It is not detectable to humansand in highconcentrations it can kill them within minutes.CO is found as one of the impurities in nitrogen and oxygen gas cylinder. A case study on determination of CO as impurity has been done in high purity nitrogen gas cylinders.A high purity Nitrogen (>99.999%) gas is used as a balance gas for preparation of calibration gas mixtures which areused for the calibration of ambient monitoringinstruments and also used in food packaging because it slows food deterioration and improves longevity. Trace gases impurity like moisture (H_2O), methane (CH_4) and carbon monoxide (CO), oxygen (O_2) effectively change composition of standard gas mixtures by reacting with required component gases or by adsorbing on cylinder surface. Cylinder pressure plays an important role in industrial and medical purposes because the concentration of impurities increases when cylinder pressure decreases whichmay be highly dangerous in medical field. A different type of techniquesare used like FTIR, GC-FID, GC-PDHID or CRDSetc for impurities measurements. In which Cavity ring down spectroscopy (CRDS) technique for laser spectroscopy is a relatively recent development and is considered as primary method that measures impurity levels directly without need for calibration gases.In cavity-enhanced absorption spectroscopy, the laser light is guided into an optical cavity with two highly reflective mirrors with a reflectivity greater than 0.999. A light pulse from a tunable pulsed laser enters a cavity and travels back and forth between the mirrors, which increases the absorption length by several orders of magnitude.These profound path lengths provide ppb detection range for analyte gases. Measurement of CO gasin high purity nitrogen gas is done by CRDS analyzer. CO impurityis also determined by gas chromatograph using flame ionization detector which was in agreement with CRDS results. Lowest detection limit of CRDS used is1 ppb for CO measurement. The observed concentration of CO was found to be <1 ppm at high pressure gas cylinder (~200 bar) buta spike change in concentration was observed atlow pressure (~50 bar) i.e. 2-3 ppm. Measurement uncertainty is also evaluated for the analysis.

Key words: Gaseous pollutants, Cavity Ring down Spectroscopy (CRDS), Effect of pressure, Effect of CO in human health, Measurement uncertainty.

General Presentation

OP-1

Oral Presentation

Seasonal Assessment of Ground Water Toxicants from Fatehpur Shekhawati block of Rajasthan

Anurag Kadwasara, Pravinkumar and Anurag Choudhary*
Assistant Professor, Department of Chemistry, JNV University, Jodhpur
anurag051981@gmail.com

Water is one of the most important natural resource in the universe and an essential compound for life having its prime uses in drinking and irrigation. The most common problem associated with water is identified with the presence of some toxic ions such as fluoride, nitrate and arsenic.

Ground Water samples were collected from 49 different sites of Fatehpur Shekhawati block of Sikar district Rajasthan from various sources to evaluate some physicochemical parameters such as fluoride, chloride, nitrate, TDS, Alkalinity, pH and hardness. Fluoride, nitrate and chloride content was found in the range from 1.6-11.8, 2.0- 480 and 190-800 mg /L respectively.These results indicate that toxic contents in ground water samples were found beyond the permissible limits governed by WHO and BIS standards which are responsible for negative health and environmental impacts.

Bio-adsorbents have come up as one of the promising substances which can remove or minimize the different type of toxic organic and inorganic pollutants present in industrial waste as well as in Groundwater. For this purpose our research is focusing on peanut shell as agricultural bio waste which is subjected to physical and chemical modification to obtain more advantageous product for water treatment.

Keywords: Ground water, bio-adsorbents, peanut shell.

OP-2

Biodegradationof Textile Dye by Fungal Species Isolated from Contaminated Industrial Sites of Hapur District, Uttar Pradesh

Dr. Riti Thapar Kapoor
Assistant Professor, Amity Institute of Biotechnology, Amity University, Noida - 201 313, Uttar Pradesh, India
rkapoor@amity.edu

The presence of dyes in wastewater released from manufacturing units represents a major environment problem. Industries such as textile, paper, printing, plastic and leather etc. are consuming huge amount of dyes to colorize their products. Most of the textile and dye manufacturing industries pours dye contaminants directly into water resources without any treatment which may pollute both ground water and soil. It has been estimated that around 10-15% of the dyes used in the industries are lost in the effluents during the dyeing operations. The physical and chemical methods such as coagulation, chemicaloxidation, membrane separation, ion-exchange, photo-catalysis, reverse osmosis and adsorption have been used to deal with dye pollutants. The major drawback associated with all the above mentioned techniques is high cost of application, intensive energy requirement, complex procedure, unable to completely remove the dyes and generation of sludge which causes secondary pollution.

The present investigation was conducted to evaluate the dye degradation potential of indigenousfungal isolates such as *Aspergillus niger, Aspergillus flavus, Fusarium solani* and *Fusarium oxysporum* collected from contaminated soils of effluent disposal sites of industrial area of Hapur district of western Uttar Pradesh. The effect of different factors viz. pH, temperature, inoculum size, incubation period and dye concentration was studied on the dye degradation process. The results revealed that indigenous fungal species exhibited high dye removal efficiency which significantly decolorized dye contaminated effluent. Further researches are required to develop cost-effective decentralized wastewater treatment system for small or medium scale manufacturing units.

OP-3

Impact of Pesticides on Soybean Plants in Madhya Pradesh

Kishor Kumar Pal[1], Lallan Kumar Tiwary[2]
"[1,2]Department of Chemistry, Regional Institute of Education, Bhopal(M.P)"
kishorkumar_pal@yahoo.com

Madhya Pradesh is a land of agriculture where pesticides, insecticides and varieties of fertilizers are extensively used. The pesticides consumption causes a serious environmental and public health problem. Due to steep competition many farmers make overuse of organophosphate pesticides to increase their agriculture yields.

The Farmers involved in the spraying activities of pesticides in the field get direct exposure of pesticides due to unsafe and no preventive work practices. They do not use safety masks, gloves and other protective gears during the spraying of pesticides which results into the access of pesticides in the blood stream through inhalation and dermal exposure which adversely affect their eyes, skin and the respiratory system. It was observed that the increased rate of pesticide treatment significantly decreased Physiological parameters like rate of photosynthesis transpiration. It has also been observed that this photosynthesis transpiration is significantly decreased with increased concentration of pesticide in soybean plants. The Stomatal conductance has also been found to increase at higher concentration of pesticide T4 in soybean. The impacts of foliar spray of pesticide on growth and metabolism of Soybean has been studied under controlled condition using chlorpyrifos.The study shows that the pesticides can significantly affect the plant growth and yield of soybean. A growing number of soybean producers have begun to incorporate below threshold fungicide, insecticide and pesticide treatments into their management programme in attempt to increase their yield.

*sneogi@csmcri.res.in

Rapid consumption of fossil fuels has increasedthe concentration of carbon dioxide (CO_2) beyond the permissible limit.Consequently, CO_2 capture and sequestration (CCS) is major research goal with specific importance to develop new functional materials for selective capture and catalytic fixation of CO_2.The non-toxic and anthropogenic CO_2 serves as a potential C1 source towards 100% atom-economic conversion of CO_2 to cyclic carbonates, which find enormous applications.The high surface area, compositional diversity and tailorablepore characters in metal-organic frameworks (MOFs) endorsethese porous crystalline frameworks ideal candidates for adsorption of major green-house gas as well asheterogeneous catalysis. In this direction, we have strategically designed Cd(II)-framework Cd1.5(L)2(bpy)(NO_3)]•$_2$DMF•2H_2O (CSMCRI-5) (HL = 4-(4-carboxyphenyl)-1,2,4-triazole, bpy= 4,4′-bipyridine, DMF = Dimethylformamide), by utilising the bifunctional ligand HL. Thefunctionalised and optimum sized poresin this two-fold interpenetrated structure provides ample basic nitrogen sites for highly selective and multicyclic adsorptionof CO_2. In another case, a chemically robust Zr(IV)-based framework (ZrOF) was synthesized, andfurther modified through incorporation of ultra-small Ni-nanoparticles. Despite reduction in surface area, the CO_2 adsorption capacity increased tremendously with a large rise in adsorption enthalpy.The Ni@ZrOF system was utilised as a highly active heterogeneous catalyst towards solvent-free fixation of CO_2 to cyclic carbonates in excellent yield under relatively mild conditions. Both of these materials exhibit remarkablerecurrences towards CO_2 adsorption and catalysis for multiple cycles.

Keywords: Robust metal-organic framework, post-synthetic modification, CO_2 adsorption, cyclic carbonate, mild conditions

Theory of Waste Water From Boil Rice Mill Unit By Concentration

Mrs. Sushma Sharma
Research Scholar, Kalinga University Kotni Naya Raipur (C.G), India
biplab2409@gmail.com

Above 260 rice mills are obtainable in the Raipur district in Chhattisgarh considering the main supply of this area is paddy which was change within rice, rice mill are need for the activity, the sector like Raipur and Chhattisgarh are too much devoted to with this sector and the mostly human are very focused in per-boiled paddy the summer plants are also devoted to these paddy mills. Water is the most specific element in the before cleaning the paddy and after per-boiling the waste water is manufacture of which the reception is requisite prabhu rice mill Nawapara Rajim was choose for the waste water study from parboiled paddy unit by concentration waste water was composed from two or three samples of the rice mill by seize selection

OP-6

Albumin Protein derivedSustainable Underwater Superoleophobicity

Arpita Shome and Uttam Manna*
Department of Chemistry,Indian Institute of Technology, Guwahati, Assam – 781039
arpitashome2@gmail.com

Fish-Scale inspiredunderwater superoleophobicity is the ability of an interface to repel an oil droplet underwater, that has been widely adapted artificially in the past for diverse applications including oil droplet manipulation underwater, oil/water separation, self-cleaning etc. However, the synthesis of a highly durable bio-inspired underwater superoleophobic coating is of utmost importance for achieving uninterrupted performance at practically relevantand challenging conditions. In the current design, bovine serum albumin (BSA) protein was deposited on a fibrous substrate followed by 'in situ' treatment with glutaraldehyde to achieve a cross-linked imine-based fluorescent coating.[1] The resultant interface displayed uninterrupted underwater oil repellence even after 30 days exposure to highly alkaline (pH 12) water, surfactant-contaminated water, river water and sea water. However, due to accelerated hydrolysis of imine under acidic conditions, the embedded underwater "superoleophobicity'' transformed into "oleophobicity'' on exposure to acidic conditions for 12 h. To combat this challenge, the reductive conversion of imine to secondary amine was adopted in the BSA-derived coating. The resultant coating embedded with underwater superoleophobicity survived different severe physical abrasionsand 30 daysexposure to pH 1, pH 12, seawateretc. Further, such a durable coating was extended for environment friendly separationof the chemically contaminated aqueous phase from both refined oil and crude oil with water collection efficiency above 98 v/v %. Thus, this simple and scalable chemical approach provided a platform for developing a highly sustainable underwater superoleophobic coating, which can perform under challenging scenarios.

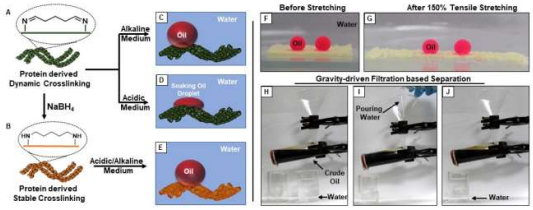

Figure 1. The facile and dynamic cross-linking process between the amine residues of bovine serum albumin protein and glutaraldehyde yielded a fluorescent coating (A) on a fibrous substrate that displayed underwater superoleophobicity in alkaline media (B) but failed to perform in acidic media owing to the hydrolysis of the imine (C). The reduction of the imine bond resulted in a stable cross-linked BSA coating (D) that continued to display unperturbed underwater superoleophobicity in both acidic and alkaline media (E). F-G) The oil repellence underwater remained intact even after 150% tensile stretching of the coating. H-J) The reduced imine based BSA-coated membrane was pre-exposed to crude oil (H), and thereafter, on pouring the water phase through the funnel (I), the added water selectively permeated through the membrane in the gravity-driven filtration-based process (J).

gproy@iittp.ac.in; gouriroyiisc@gmail.com

Methylmercury ($MeHg^{+}$) is a potent neurotoxin that bio-accumulates at high levels in food chains, and thus poses a significant health risk to human.It is known to inhibit several important antioxidant enzymes and also reduce the concentration of endogenous thiols likecysteine and glutathione in tissues, and thereby increases the production of reactive oxygen species which lead to the oxidative damage of biomolecules including DNA and protein.The high potency of $MeHg^{+}$ in producing DNA damage compared to inorganic mercury Hg^{2+} in tissues isoftenrecognized due to its striking ability to easily cross the cellular membranes including the placental and blood-brain barriers.However, contrary to its recognized indirect role on oxidative DNA damage,in this oral presentation for the first time we will show the direct effect of $MeHg^{+}$ on DNA damage, in addition to the oxidative DNA damage, which may account for its highly cytotoxic compared to inorganic mercury.[1,2]

Keywords: Methylmercury, Alkylative DNA Damage, Oxidative DNA Damage.

prasun.mondal70@gmail.com

Trends of monthly variation of concentrations of ambient air quality parameters in the KMC area are analysed during the three years of 2003-2004, 2008-2009 and 2009-2010. Using statistical analysis, Outlier test of monthly concentrations of PM10, SO_2 and NO_2 during the three years shows that 0.42% data is statistically unsatisfactory and 0.16% data is statistically as well as environmentally unconsidered. For PM10, monthly variation of concentration shows similar wavy trends during these three years. This similarity in variation of concentration is supported by the statistical analysis as there exists strong non-linear Spearman correlation for PM10 concentration between the years 2003-2004, 2008-2009 and between the years 2003-2004, 2009-2010. For SO_2, monthly variation of its concentration was observed to show nearly linear trend during the years of 2003-2004, 2008-2009 and 2009-2010. Also, statistical analysis shows that SO_2 concentration of the year 2003-2004 has strong linear Pearson correlation with that during the year 2008-2009 as well as during the year 2009-2010. During the three years, monthly variation of NO_2 concentration shows nearly similar trend. However, contradictory interpretation is observed as NO_2 values has Spearman correlation between the years 2003-2004, 2009-2010 and Pearson correlation is observed between the years 2003-2004 and 2008-2009. Also, paired sample t-test shows correlation in NO_2 concentration between the years 2003-2004 and 2008-2009 only.

Anion exchange membranes for eco-friendly and sustainable energy devices

Gaje Singh and Dr. Debaprasad Mandal*
Department of Chemistry, Indian Institute of Technology Ropar, Punjab-140001, India
gaje.singh@iitrpr.ac.in, dmandal@iitrpr.ac.in

Incessant exploitation and exhaustion of limited natural energy sources and related technologies pose a threat to the environment and the global economy. Natural energy sources are associated with various environmental implications like pollution and global warming leading to conspicuous climate change. At the same time, 88% of the current energy economy relies on fossil fuels[1]. Despite the outsized share of conventional energy sources to the energy portfolio, it is time to get rid of the era of fossil fuels. But there is no globally accepted benchmark of resource availability for long-term energy planning purposes. Natural energy sources seem to be the solution to this energy constraint or crisis but the intermittent nature and latitude dependency of these sources are the roadblocks to their full employment at the global level.[2] Hydrogen is the most abundant element in the universe with no toxicity, high mass- energy density (39.4 kWh kg^{-1})[3], and high energy efficiency (>70%).[4] Thus, the hydrogen produced from renewable energy sources used as fuel can be considered as a promising replacement for fossil fuels. So, both Electrolyzer and fuel cells together in conjugation with renewable energy sources are recognized as a key technology in the delivery of clean energy with low emission, high efficiency, and scalability[5, 6]. These technologies rely on Ion exchange membranes (IEMs). Alkaline anion exchange membranes (AAEMs) are viable alternatives of proton exchange membranes (PEMs) and are the center of attraction owing to the extra benefit of faster oxygen reduction kinetics (ORR) and the use of non- noble metals. AAEMs based technologies are at their infancy stage and require impactful exploration for commercialization. Here we will discuss per substituted imidazolium based AAEMs which shows appreciable conductivity and alkaline stability.

A Review On Effective Heterogeneous Catalysts For Biodiesel Production

Niraj S. Topare*, Dinesh S. Bhutada
*School of Chemical Engineering, Dr. Vishwanath Karad MIT World Peace University, Pune-411038, India
niraj.topare@mitwpu.edu.in, nirajtopare06@gmail.com

Rising demand for energy and environmental issues associated with depleted fossil fuels have led to the requirement for an alternative source of renewable energy. Generally, biodiesel processing is carried out by the trans esterification reaction process. The production of biodiesel is commonly carried out by trans esterification reactions, catalyzed by homogeneous or heterogeneous catalysts. In the reaction steps, several parameters have been evaluated, such as catalyst quantity, alcohol molar ratio: oil, temperature, agitation speed, and duration of reaction. The trans esterification reaction of several raw materials as sources of feedstock, various alcohols, and heterogeneous catalysts is therefore presented in this review. Optimal conditions have been summarized for each catalyst, as well as its respective mechanisms of reaction.

Keywords: Biodiesel, heterogeneous catalyst, operating parameters, transesterification

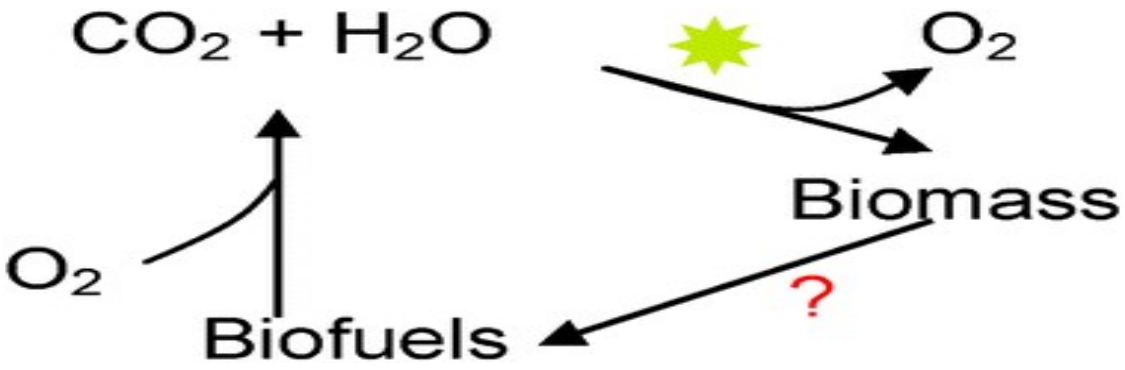
"Bio Fuels & Green Chemistry- A New Horizon"

Mr. Soumya Sinha Roy
Faculty, Department of Chemistry, Polba Mahavidyalaya, Hooghly, West Bengal, India.
sinharoysoumya@gmail.com.

Nature provides a remarkably wide range of renewable raw materials with varying properties and differing chemical compositions. Renewable raw materials are therefore especially interesting as alternatives to fossil resources for energy generation and as starting materials for industrial chemistry. Bio fuels (and bio fuel additives) have been known since ancient times. In fact, more than 100 years ago, the two giants of modern car engine, Henry Ford and Rudolph Diesel, strongly believed in the future of bio fuels, and began with ethanol and vegetable oils to run the Ford Model-T and the diesel engine, respectively. With the significant increase in the importance of oil, the technologies based on the use of bio fuels were set aside. Nowadays there is an urgent need for the reduction of fossil fuels consumption, as already mentioned, but at the same time, innovative chemical production is fundamental for keeping the level of civilization high and opening new job positions.

Keywords: biomass; green chemistry; bio diesel; renewable.



OP-12

One pot synthesis of bicyclic heterocycles Benzothiazepines: Green Approach

Madhuri Kandalkar and Priyanka Sharma
Department of Basic & Applied Sciences, School of Engineering & Sciences GD Goenka University, Gurugram
madhuri.keote@gmail.co

Green chemistry deals with chemical processes that are environmentally sustainable in the long run. The idea of 'going green' is to look at all the processes from source to sink that determine and follow the processes that will reduce the impact of harmful chemicals in the environment. The subject encompasses the resources of raw material, manufacturing techniques and processes, water and energy use in such processes, waste generation and disposal of waste and final product export out of the manufacturing unit. Greener reactions are especially important in organic chemistry, where, due to a huge number of industrial processes with the use of hazardous chemicals and solvents, severe damage to the environment takes place. In organic chemistry, green techniques include reactions of C–H bond activation, fluorous, solid-supported, bio- and asymmetric catalysis and synthesis, use of water and other green solvents in particular, ionic liquids or without any solvent, microwave, ultra sound and ultraviolet (UV)-assisted reactions, and use of flow reactors. Several non-contaminating physical methods, such as microwave heating, ultrasound assisted and hydrothermal processes or ball milling, frequently used in combination with the use of natural precursors.

The endeavor of the research work is to develop more effective synthetic procedure for synthesis of new active benzodiazepine and benzothiazepine derivatives using milder, selective, nonhazardous and inexpensive solvents. One pot synthesis is an approach for the synthesis of 1,5- benzothiazepines with the features like high yield, very short reaction time, no side products, no solvents, does not require critical purification and separation. The methodology employed is most superior over conventional methods of synthesis, since it is convenient, minimizing waste, equipment, energy, eco-friendly and demand of the generation for sustainable development.

Multifunctional Arithmetical Processor inside GUMBOS

Pallobi Sarkar and Sudhir Kumar Das
Department of Chemistry, University of North Bengal, Darjeeling-734013
pallobisarkar0040@gmail.com

To construct future molecular computers, the mimicry of some elementary functions of neurons and electronic computers at the molecular scale has been attracting more and more interest from chemist community. Many life processes, such as chemical synapses of neurons, can operate normally within a very narrow ion window such as Ca^{2+} and H^{+}. This function or behavior can be described as being "off-on-off" or "on-off-on" behavior as a function of ion concentration. Mimicry to this behavior at the molecular scale has been possible for some time with Ca^{2+}, H^{+}, or laser as inputs. These studies are highly important not only for the understanding of complex mechanisms of important life processes but also for the potential application in molecular computing. Presently, we are interested in exploring a single molecular species to execute distinct algebraic operations, even to mimic some elementary functions of neurons by a variety of chemical inputs by exploiting the advantage of GUMBOS-group of uniform materials based on organic salts. Maintaining input ion concentration,depending on the corresponding signals (output), keeping the output above a threshold value we will see definite output signals in UV-Visible regions in the form of two 1 & 0 i.e. ON &OFF respectively. If we get outputs as ON--OFF-ON mode, we can conclude in two input system, if we reverse the inputs the output may be ON-ON-ON mode form this obviously we cannot make any conclusion visually. This is how encryption, coding, decoding molecular systems can be formed.

Low cost adsorbent prepared from waste plant material for removal of congo red dye from wastewater

Bhanupriya Mordhiya[1], Chetan Selwal[2]
[1]Department of Chemistry, University of Rajasthan, Jaipur (Rajasthan)
[2]Department of ECE, Government Women Engineering College, Ajmer (Rajasthan)
bmordhiya@gmail.com

The adsorption process is being extensively used for the removal of dyes from synthetic dyehouse effluents. The most widely used adsorbent is commercially available activated carbon. Despite the frequent use of adsorption in wastewater treatment systems, commercially available activated carbon remains an expensive material. The safe and economical methods are required for the treatment of dyehouse effluents. In recent years, researchers are focussing towards the preparation of low cost adsorbents from cheapest sources like waste plant materials. Therefore, in this research paper stems of Prosopis cineraria (Kejri) was used to prepare activated carbon for removal of congo red dye from aqueous solution. The dye adsorption experiments were carried out by using bath procedure. UV-visible absorption spectroscopy was used to record the adsorption behavior. The pH effects, the contact time and the initial dye concentration were changed to obtain the best experimental conditions. The dye adsorption equilibrium was attained after 60 min of contact time.

Keywords: Adsorption, Wastewater, Prosopis cineraria, Congo red dye, Low cost adsorbent.

OP-15

Treatment of Wastewater of Textile Industries Using Photocatalyst

Uses of photocatalytic techniques for decomposition of azo dyes those are non- biodegradable and persistent in water for longer duration. Complete removal of dye contaminant from water is challenging. This water dye contaminated water is also dangerous for living beings as azo dyes are carcinogenic in nature. Application of photocatalytic techniques for the degradation of these dyes would be beneficial and cheaper than conventional treatment technologies. photocatalyst has great potential of degradation of organic pollutants within a few minutes of treatment. We used the azodye model (commonly used in textile industries) for experimental purposes. We observed successful depredation of sample azo dyes by the photocatalyst.

Keywords: Degradation; Azo dyes; photocatalyst

Application Of Chemically Modified Di Thiazide- Chitosan For Adsorption Of Industrial Toxic Metal Ions

Sardar Singh Pooniya and Anurag Choudhary
Department of Chemistry, JNV University, Jodhpur
anurag051981@gmail.com

In recent decades, acceleration of modern industrial activities have introduced environmental pollution in view of heavy metal ions which has reached at alarming level in aquatic and terrestrial environment and therefore, concerned the contemplationto many researcher groups worldwide due to its adverse effect on human and animal life.

Chitosan is a (Poly-ß-(1,4)-2-amino-2-deoxy-D-glucose which is a nitrogenous (amino base) polysaccharide, Due to unique polycationic nature, controlled biodegradability, biocompatibility, nontoxicity and bioresorbable nature, it has several key properties that make it one of the most promising natural substances in environmental field. Chitosan is highly acquiescent to chemical modification via one of its three reactive functional groups: the amino group as well as both primary and secondary hydroxyl groups. Chemical modification, in particular crosslinking and grafting of these polysaccharides offers vast opportunities to be used as bio adsorbents for pollutants.

Investigation has been done for chemical modification of chitosan through di thiazole compound. Chemically modified chitosan was applied for adsorption of industrial waste effluents through adsorption process. The process was followed by Langmuir and Frendlich isotherm through batch experiments.

Keywords: Chitosan, industrial effluents, adsorption.

Study of Change in Physico Chemical Parameters by Treatment of Sludge from Common Effluent Treatment Plant (CETP) with Earthworm

S. Maheshwari *, P. Kriplani *, A. S. Jethoo **
*Department of Chemistry, Govt. Women Engineering College Ajmer-305002 (India)
**Department of Civil Engineering, Malaviya National Institute of Technology, Jaipur – 302017 (India)
email seemamaheshwari@gweca.ac.in

One of the most vital problems of environmental protection concern is that of solid waste disposal as the inappropriate disposal of CETP's hazardous sludge can cause serious environmental problems. The sludge if sent for land filling may cause ground water contamination, changing the soil fertility parameters as well. The research presented here is carried out to explore the ability of an epigeic earthworm Eudrilus eugeniae to transform the sludge produced from CETP into value added product i.e., vermicompost. In this study, six samples of feed mixture were used with different ratio of CETP sludge, cow dung and saw dust. Physicochemical parameters such as pH, Electrical Conductivity (EC), Volatile Solids (VS), Total Nitrogen (TN), Nitrate Nitrogen (NO^{3-}-N), Ammonium Nitrogen (NH^{4+}-N) were characterized to analyze the quality of the compost formed. All these parameters are in the agreement with recommended standards of the mature compost. The result shows that vermicomposting technique when used epigeic earthworm Eudrilus eugeniae can work as a favorable alternative solution for disposal of CETP sludge.

Keywords: Common effluent treatment plant sludge, Eudrilus eugeniae, vermicompost, cow dung, saw dust, pH, Electrical Conductivity (EC), Total Nitrogen, Phosphorus.

Due to high cost of culture media used for microbial growth is creating complications in the scaling-up of biological processes in wastewater treatment. The experiment is designed to find a beneficial, inexpensive and effortlessly available alternative source for culture growth and removal of heavy metals and present work highlights the use of bark material of Azadirachta Indica (neem), Psidium Guajava (guava), Vachellia Nilotica (acacia) and Saccharum Officinarum waste (bagasse) for biofilm preparation and used as Cr(VI) and Pb reduction. In this experiment an indigenous heavy metals reducing bacterial strain P8 isolated from Motha River, Kakasaheb Gadgil Bridge, Deccan, Pune, Maharashtra and identified as Bacillus subtilis strain JCM 1465 MN749805.1 on the basis of 16S rRNA gene sequencing. Selected isolate is not even accumulate the lead but also capable for conversion and accumulation of 8 mM solution of hexavalent chromium into 0.35 mM trivalent chromium. Based on maximum fixation capacities of lead and chromium, bark materials could be arranged as Saccharum Officinarum>Psidium Guajava>Azadirachta Indica>Vachellia Nilotica. The performance of different biofilms prepared by identified bacterium in lead accumulation is Saccharum Officinarum>Vachellia Nilotica>Psidium Guajava>Azadirachta Indica. Similar biofilms performance in chromium bioaccumulation is as Vachellia Nilotica>Saccharum Officinarum>Psidium Guajava>Azadirachta Indica.

Optimization of Different Organic Solvents For The Fabrication of Uniform Graphene Oxide Thin Films Through Langmuir-Blodgett (LB) Technique

Samridhi Chopra[1,2] and Ved Varun Agrawal[2]
[1]Academy of Scientific and Innovative Research (AcSIR), Council of Scientific and Industrial Research-Human Resource Development Centre Campus, Ghaziabad, Uttar Pradesh.
[2]CSIR-National Physical Laboratory, Dr. K. S. Krishnan Marg, New Delhi-110012, India.
choprasamridhi0@gmail.com

The main focus of the work has been to optimize the organic solvent for the utilization in Langmuir-Blodgett (LB) technique to synthesize uniform graphene oxide thin films and the study of the fabricated thin films through Atomic Force Microscopy (AFM). Graphene Oxide has been synthesized through Modified Hummer's method and characterized through UV-Visible Spectroscopy, Fourier Transform Infrared (FTIR) Spectroscopy, X-Ray Diffraction (XRD) Spectrum, Raman Spectrum, and Zeta Potential Distribution. As-prepared Graphene Oxide has been dispersed in THF (Tetrahydrofuran), *N*-methyl-2-pyrrolidone (NMP) with Cyclohexane and Water: Methanol mixture in varying ratios and volumes and their Pressure (π)-Area Isotherm have been recorded through Langmuir-Blodgett (LB) system. Although THF and NMP with Cyclohexane gave satisfactory isotherm results but Water: Methanol mixture accounted for the suitable Pressure (π)-Area Isotherm for the deposition of Graphene Oxide thin films. Films of all three solvent mixtures have been collected on glass and silicon substrate through Langmuir-Blodgett trough and studied under AFM, that showed although, THF and NMP with Cyclohexane gave graphene oxide films on the substrates but not that much uniformity has been found as it has been in the case ofWater: Methanol mixture. Further, 1:5 Water: Methanol mixture has been utilized to form more films and studied under AFM.

Keywords: Langmuir-Blodgett (LB) Technique, Graphene Oxide, Atomic Force Microscopy(AFM).

Determination of traces of toluene by simple chemical oxidation method

Gazal[1,2], Daya Soni[1,2]* and Prabha Johri[1,2]
[1]Academy of Scientific & Innovative Research (AcSIR), CSIR- National Physical Laboratory Campus, New Delhi – 110012, India
[2]Environmental Sciences & Biomedical Metrology Division, CSIR- National Physical Laboratory, New Delhi – 110012, India
*dsoni@nplindia.org

Toluene is an aromatic hydrocarbon commonly used as octane – boosting component in gasoline blending, raw material in the production of other chemicals (benzoic acid, toluene diisocyanate), as a solvent in paints & coatings, inks, adhesives, pharmaceuticals. Toluene exposure occurs especially in occupations such as printing or painting where toluene is used as a solvent. Inadvertent sources include emissions from motor vehicles & aircraft exhaust, losses during gasoline marketing activities, chemical spills & cigarette smoke. It is a member of the BTEX group of pollutants that are exerting influence on global environmental problems. In the presence of sunlight and oxides of nitrogen in the atmosphere, toluene is considered as precursors for ground level ozone and secondary organic aerosol formation. EPA has labeled toluene as hazardous air pollutant (HAP) and a toxic substance. Inhalation of toluene in low to moderate levels can cause tiredness, confusion, weakness, drunken-type actions, memory loss, nausea, loss of appetite, hearing loss, and color vision loss. Current methods for analyzing BTEX are via gas chromatograph equipped with flame ionization detector (FID), photo ionization detector (PD-HID), and solid–phase microextraction (SPME) followed by GC- MS. Disadvantages of these methods include elaborate sampling and advanced instrumentation. So, our present study includes the development of a chemical method for toluene estimation. On this account, pure toluene was oxidized by $KMnO_4$ in a basic medium that converts into potassium benzoate which is analyzed by UV-Spectrophotometer, and % age of conversion is determined. Different concentrations of potassium benzoate obtained by applying reaction on different amounts of toluene is analyzed that gives wavelength maxima at 223.5nm (same as that of pure potassium benzoate purchased from Merck), the exact amount of toluene in the sample can be quantified. Limit of detection for this method is 0.1ml/87mg toluene. It gives estimation of toluene in sewage water disposal, which provides very high sensitivity and accuracy that would be ideal for this kind of analysis.

Keywords: Toluene sources and effects, BTEX analysis, oxidation of aromatic compounds, UV-Spectrophotometer

Synthesis of Polymer Coated MCM-41 Nanohybrid And Its Application In Antibacterial, Antioxidant And Drug Delivery

Ruby Kumari*, S.S.Narvi & P.K.Dutta
*Department of Chemistry, Motilal Nehru National Institute of Technology Allahabad 211004, Uttar Pradesh ,India
*Email of Presenter: ruby27993@gmail.com

Mesoporous silica nanoparticles (MSNs) and chitosan are biocompatible due to their unique properties and also made outstanding achievements in the field of biomedical applications. In the present work, thiolated chitosan (organic polymer) was coated on 3-(trimethoxysilyl)-1-propane thiol (TMSP) modified MCM-41 (inorganic silica) through disulfide bond by oxidation process or oxidative coupling. The synthesis of chitosan-silica based hybrid material was confirmed by FTIR, XRD, SEM, TGA and NMR techniques. FTIR spectra peaks at 545cm^{-1} corresponds to disulfide linkage and thiol groups peaks at 1258cm^{-1} (S-C bond) and 2580cm^{-1} (H-S bond). The SEM images exhibits change in the surface morphology of hybrid which confirm the successful coating of polymer onto silica surface and XRD patterns of MSNs at 2θ=2.5° corresponds to differaction peaks of hexagonal mesoporous structure. The antibacterial properties observed that gram-negative (E. coli) bacteria exhibit better inhibition zone (2.8, 2.4, 2.0, and 1.8 cm) than gram-positive (B. subtilis) bacteria (2.4, 2.1, 1.6 and 1.4cm). The DPPH scavenging capability of synthesized hybrid was found to be 67.48%. The drug (quercetin) encapsulation efficiency of hybrid material was calculated to be 92.14% and more drug releases in acidic medium than that of pH7.4, so we can conclude that hybrid material shows pH-dependent drug releasing behavior. The results show that synthesized hybrid materials possess good antibacterial and antioxidant activities and also a good nanocarrier for drug delivery application.

Keywords: Mesoporous silica nanoparticles (MSNs), Chitosan, disulfide bond, oxidative coupling.

[#]Academy of Scientific and Innovative Research (AcSIR), Gaziabad-201002, U.P, India
E-mail: crpatra@iict.res.in

In the currentstudy, Prussian blue (PB) and silver salts (silver nitrate) were incorporatedin the presence of PVP [poly(N-vinyl-2-pyrrolidone)]to producestable silver hexacyanoferrate nanoparticles (silver Prussian blue analogue: $Ag_3[Fe(CN)_6]$ abbreviated as SPBANPs)[1-2]. It is an innovative nanoparticle formulated with an intention for an effective as well as safer approach of treatment strategy (2-in-1) for both cancer and bacterial infections. The characterization of the biocompatible and stable nanoparticles was done through several available techniques.The nanoparticles on application over cancer cells MCF-7, A549, B16F10and SK-OV-3) *in vitro* displayedestimable inhibition property. Moreover, when the only nanoparticles without any drug was injected in the aggressive murine melanoma model: B16F10 (C57BL6/J mouse) intraperitonially it disclosed relative inhibition of tumor growth as compared to control. Further, the SPBANPs demonstratedclear antibacterial activity in many Gram-positive and Gram-negative bacteria. The beauty of this current nanoformulation is that it itself functionsfor drug delivery, as anticancer as well as an antibacterial agent. All the performed experiments (both *in vitro* and *in vivo*) collectively exhibit that this biocompatible SPBANPs devoid of any antibiotic and anticancer drug could be explored for the advancement as a multifunctional therapeutic molecule (2-in-1) for treatingcancer along with bacterial infections in the forthcomingperiods.

Hydrocarbon Class Type Data on Petroleum Resids by TLC-FID and Open Column Chromatography Techniques For Increased Predictability of FCC Modelling Software

Chandan Kumar Karan*, Anil Yadav, J. Christopher, G.S. Kapur
Indian Oil Corporation Limited, Research and Development Centre, Sector-13, Faridabad, Haryana (India)
*Correspondingauthor: karanck@indianoil.in

Fluid catalytic cracking (FCC) is one of the most important conversion processes used in refineries. This process converts heavy petroleum fractions into lighter, higher-value products, such as gasoline, propylene and others. FCC units (FCCUs) have the flexibility to process a wide range of feedstocks, and at varying severities, to optimize refinery profitability. Some of the feed stocks being processed at Indian oil refineries include SRVGO, VGO, Hydrotreated VGO, Vacuum Resids and theirblends.

In any refining processes including FCC, modeling and simulation have critical importance for process development, control, and optimization. In COVID-19 pandemic times, because of decline in gasoline demand growth, forward-looking refinersare exploring new revenue options and shifting to petrochemical-oriented operations. Refineries are turning their FCC units towards maximization of propylene and ethylene production to maintain their competitiveness. However, the simulation software for any refinery process used to optimize refinery conditions have prerequisite of precise input of analytical data onfeed.

In this work, two different methods; TLC-FID based IP 469 method and open column liquid chromatography have been used to give the precise composition of hydrocarbon classes namely - Saturates, Aromatics, Resins and Asphaltene in different kind of High boiling Petroleum Resids. To further confirm the precision of data, repeat analysis were carried by TLC-FID on each sample. The repeatability data show that standard deviations are less than 3% in estimation of each class. The data was also generated under slightly different analytical conditions of gas flow rates and change of stationary phase sets that is chromarods to check the robustness of TLC-FID based data.

Keywords : TLC-FID, FCC, Hydrocarbon class

First-Principlesbased Theoretical Investigation Of Impact Of Polyolefin Structure On Photo-Oxidation Behaviour

Vikas Khatri[a], Gurmeet Singh[b],*, and Hemant K. Kashyap[a]*
[a]Department of Chemistry, Indian Institute of Technology Delhi, Hauz Khas, New Delhi 110016, India
[b]Petrochemical& Polymer Department, R&D Center, IndianOil Corporation Ltd., Sector-13, Faridabad 121007, Haryana, India
* singhgurmeet@indianoil.in, hkashyap@chemistry.iitd.ac.in

Degradation of polyolefins is a serious issue with economic and environmental implications, and therefore we have focused on understanding the changes that occur at the molecular level during the photo-oxidation. However, polyolefins on longtermexposure to ultraviolet (UV) radiation or high-temperature conditions or erosion undergo degradation and generatemicroplastics.The microplastics generated after the degradation of these polyolefins are hazardous for the ecosystem. We have carried outDFT studies to investigate the photodegradation of sixdifferent polyolefinsranging from polyethylene to polydecene. Herein, we have investigatedphoto-oxidized derivatives of different polyolefins and analyzed theirrelative stability, conformations, UV-visible spectral behaviourand carbonyl index.The TD-DFT analysis confirms thatphoto-oxidizedproductsshow absorption peak in IR and visible region, acting as light-absorbing species.The computed results suggest that polyolefins in their pristine state are stable towards photo-oxidation,but chemical impurities like carbonyl groupsmake them proneto undergo photo-oxidation,a fundamental process leading to generation of microplastics.Our results clearly demonstrate that lower polyolefinsi.e polyethylene and polypropylene, which are the highest produced polymers globally, are more susceptible to photo-oxidation than higher polyolefins that could be the leading cause of the generation of more microplastic in the ecosystem.

β-Cyclodextrin Based Highly Efficient Selective Flocculant Towards Beneficiation Of Iron Ore Slime

Priyapratim Patra and Sagar Pal*
Department of Chemistry, Indian Institute of Technology (ISM), Dhanbad, 826004, India
*E-mail: sagarpal@iitism.ac.in

Iron is the backbone of our civilised society. The source of iron is the conventional mines. During mining of iron ore, a huge number of fine particles are generating, which are known as slime. The slime is not used for steelmaking as it contains considerable amount of impurities. Therefore, the beneficiation of slime may be a worthy approach for better quality of iron ore. Herein, a functionalized β-cyclodextrin (β-CD) based flocculant has been developed. The developed material is composed of β CD methacrylate, polyacrylamide and poly (acrylic acid). It has been found that the developed material has promising selectivity towards the hematite particles and also demonstrates very fast settling of hematite particles. The developed material has been found to be an excellent material towards the iron ore beneficiation than that of the conventional flocculant starch.

Recovery of high purity chlorine from industrial waste HCl via electrolysis

Divyani Gupta and Dr. Tharamani C.N.*
Department of Chemistry, Indian Institute of Technology, Ropar, Punjab-140001, India
2018cyz0010@iitrpr.ac.in , tharamani@iitrpr.ac.in

HCl is a fundamental chemical reagent used frequently in industries for polyvinyl chloride (PVC) production. Synthesis of polyurethanes and polycarbonates produce an excess amount of HCl as a by-product out of which only 15-20% is recycled back to chlorine, leaving behind excess waste HCl which cannot be completely employed for PVC production. An energy efficient route for valorization of waste HCl towards chlorine production is electrolysis, which involves hydrogen evolving cathode and chlorine evolving anode with cell potential of -1.36 V, accounting for high power and energy consumption along with safety hazards imposed due to H_2 evolution during uncontrolled shutdown. This can be overcome by replacement of cathode with oxygen depolarized cathode decreasing the cell potential to -0.13 V wherein development of highly active, stable and inexpensive electrocatalyst is need of the hour. We have developed a Cu-doped Fe_2O_3 catalyst incorporated in nitrogen containing carbon matrix via one step pyrolysis of precursor premeditating reduced cost and eliminating complicated procedures for carbon synthesis. A superior activity with current density of 92.1 mA cm^{-2} is observed at anode and a comparable activity to state of art catalyst is witnessed at cathode underlining the potential of electrocatalyst for HCl valorization towards chlorine production.

Effects of nano materials on bioactive glass ceramics

Tamal Kanti Ghosh and Sudip Kumar Das
Department of Chemical Engineering, University of Calcutta, 92, A.P.C. Road, Kolkata-700 009, India
tkgcrnn_rs@caluniv.ac.in; skdchemengg@caluniv.ac.in

Bioactive glass ceramics (BGC) have been widely used to restoration, implants and filling defects of dental and bone.Glass ceramics can attach directly to the bone tissue via forming a biologically active hydroxycarbonate apatite (HCA) layer due to their biocompatibility, Osteoconductivity and antibacterial activity properties. HCA layer is chemically and structurally equivalent to the mineral phase of bone. BGC is a special type of biomaterials, which has the ability to form an interfacial bond to the bone through the formation of HCA layer on the surface of samples when they are implanted in the human body or in the simulated body fluid (SBF).The addition of nano particle e.g., Nano SiO_2, Nano Al_2O_3 etc. to the BGC enhances the bioactivity and mechanical properties. In the present work the synthesis, phase composition, crystallization behavior, surface morphology of bioactive glass ceramics containing (38-*X*) normal-SiO_2-28CaO-18Al_2O_3-12CaF_2-4P_2O_5-*X*nano-SiO_2 (mol%) glass-ceramics (where X = 0, 19, and 38) have been investigated. The glass ceramics were synthesised using simple melt-quench method. The microhardness value, cutting energy, and the machinability parameter havebeen determined. The *in-vitro* study has also been investigated by immersion in the sample in SBF solution. HCA layer was developed after 28 days of immersing in the SBF. The addition of SiO_2nano particlesin the specimens showed an increase in Vicker's hardness, density, and acid-base resistivity.

Microwave assisted synthesis of cellulose after its cross linking with triazine has been used for the preparation of new chelating resin incorporating methyl orange.The resin has been characterized through, moisture content, bulk density, bulk volume FT-IR, NMR, Mass Spectroscopy, SEM and EDX.The amount of metal ions retained by these resins at equilibrium was determined in terms of distribution coefficient values (Dg). The metal exchange capacity of resins at different pH wasconsidered in a batch equilibrium study on the chelation of Mn(II) metal ion. The adsorption study of Mn (II) showed maximum adsorption at pH 4.94, the value of distribution coefficient of derivative for Mn (II) at pH of maximum adsorption was 1410.25.

Keywords: cellulose, Microwave Assisted Synthesis, SEM, EDX, distribution coefficient values (Dg)

Today's Chitosan Based Biopackaging For Foods In Digitalized World

Pradip Kumar Dutta
Department of Chemistry, Motilal Nehru National Institute of Technology Allahabad, Prayagraj 211004, India
Email: pkd@mnnit.ac.in&pkd_437@yahoo.com

Recent time digitalization in every aspects of our life has been a thrust phenomena. The purpose of it may be considered from economy, marketing, environment, cleaniness and many more. As a chemist, we can think over on it & take this challenges to your profession also. Nowadays the online purchase may be taken as one of the issues on this aspect. The purchased articles are being sent with robust packaging with considering its environmental implications aslo. The packaging materials should not be the source of junk for adverse impact on environment. From that point of views, the biopackaging has been considered as a great relief, particularly for food packaging applications. Chitosan-the active biomolecule and its derivatives have a significant and very fast development in food application area because of its biodegradability, biocompatibility, antimicrobial activity, non-toxicity and versatile chemical and physical properties along with different forms of shapes like fibers, films, gels, sponges, beads or nanoparticles. The present paper will discuss on chitosan films/coating as a biopackaging material for the quality preservation and shelf life of a variety of foods and for clean environment in randomized digitalized world.

Keywords: Chitosan, antimicrobial activity, biopackaging, food application, environment, digitalized marketing

Indian Academicians Seed, Harvest, Germinate & Cultivate The Buddingpharmacists To Serve For Mankind Because Service To Human Is The Service To God

Prof. Dr.Dhrubo Jyoti Sen*
D.Pharm., B.Sc. (Hons), B.Pharm. (Hons), M.Pharm., Ph.D., FICS, CChem FIC (India), CChem FRSC (UK), CSci (UK), AOM (USA)
Department of Pharmaceutical Chemistry, School of Pharmacy, Techno India University, Salt-Lake City, Sector-V, EM-4,Kolkata-700091, West Bengal, India.

Outlook: Before you pray for life: Believe on Pharmacist Before you speak to doctor: Listen to Pharmacist Before you spend money for medication: Earn the trust on Pharmacist Before you write your consent: Think over Pharmacist's devotion Before you quit from life: Try to feel Pharmacist's noble profession Before you die: Live with Pharmacist's oath.TEACH & LEARN both are five-man army in the fieldof pedagogy. Actually T-EACH & L-EARN is the focusto EACH and every person to EARN something afterimplementation of basic knowledge which has beengrasped through the diploma [DPharm] or baccalaureate [BPharm] or postbaccalaureate [MPharm] or in doctoralcourse [PhD] in pharmaceutical science. Pharmacy is avast subject totally embedded into the application oftherapy through medication by proper nursing.Pedagogy is the discipline that deals with the theory andpractice of teaching that informs teaching strategies,teacher actions and teacher judgments and decisions bytaking into consideration theories of learning, understandings of students and their needs and thebackgrounds and interests of individual students. Pedagogy includes how the teacher interacts withstudents and the social and intellectual environment theteacher seeks to establish. A true academician is a personwho has grasping power of subject expertise and Gateway of basic knowledge has to be focused on traffic personalization. Pharmacy is subject which runs on it's two legs: chemistry & biology. An academician is a person who can correlate these two basic subjects with compilationto give best outcome of cream to the global domain byfar-sight. Reflection of elements of periodic table in pharmaceutical science through correlation approach offar-sight of pharmacy which is the vision of pharmacy (phar-sight) in globalization in past and currentmillennium. Indian pharmaceutical academician is the best contributor of basic knowledge to pharmacy practicethroughout the nation.

Pharmacists, also known as chemists (Commonwealth English) or druggists (North American and archaically,Commonwealth English), are healthcare professionalswho practice in pharmacy, the field of health sciencesfocusing on safe and effective medication use. Apharmacist is a member of the health care team directlyinvolved with patient care. Pharmacists undergouniversity-level education to understand the biochemicalmechanisms and actions of drugs, drug uses, therapeuticroles, side effects, potential drug interactions andmonitoring parameters. This is mated to anatomy, physiology and pathophysiology. Pharmacists interpretand communicate this specialized knowledge to patients, physicians and other health care providers. Among otherlicensing requirements, different countries requirepharmacists to hold a Bachelor of Pharmacy (B.Pharm.), Master of Pharmacy (M.Pharm.), or Doctor of Pharmacy(Pharm.D.) degree. The most common pharmacistpositions are that of a community pharmacist (alsoreferred to as a retail pharmacist, first-line pharmacist ordispensing chemist), or a hospital pharmacist, where theyinstruct and counsel on the proper use and adverseeffects of medically prescribed drugs and medicines. Inmost

countries, the profession is subject to professionalregulation. Depending on the legal scope of practice, pharmacists may contribute to prescribing (also referredto as "pharmacist prescriber") and administering certainmedications (e.g., immunizations) in some jurisdictions.Pharmacists may also practice in a variety of othersettings, including industry, wholesaling, research,academia, military and government.

New ^{1}H NMR method for quality control and to differentiate genuine and spurious hand sanitizers for COVID-19

Ravindra Kumar*, Sujit Mondal, J. Christopher, G.S. Kapur, S.S.V. Ramakumar
Indian Oil Corporation Limited, Research & Development Centre, Sector-13, Faridabad- 121007, India
*Corresponding author:kumarr88@indianoil.in

In light of rapidly evolving COVID-19 pandemic and demand for hand sanitizers in global and Indian markets, many companies are manufacturing alcohol-based hand sanitizers and selling in the market. Though genuine manufactures produce and supply hand sanitizers as per guidelines by World Health Organization (WHO), due to sudden demand, inferior and cheaper quality spurious sanitizers are also available in the market and not meeting the guidelines of WHO. Considering public health, there is a need for quick and reliable method to analyze the alcohol-based hand sanitizers by analytical technique for their quality. There is no single method available for estimation of all four components viz. alcohol, glycerol, hydrogen peroxide and water in the hand sanitizer formulation as per guidelines of WHO.

A quick and reliable ^{1}H NMR method was developed for quality control and to differentiate genuine and spurious hand sanitizers for COVID-19 based on proton NMR technique which can estimate all four components in WHO-recommended Handrub formulations without using any organic chemicals. Further, this method can able to identify various other toxic components present in sanitizers like methanol. In this method, hydrogen peroxide peaks were successfully separated in presence of water and alcohols. The experiment parameters were designed and the equations were derived so that all four components can be quantified without using any organic solvent in just 15 minutes in WHO-recommended Handrub formulations.

Some sanitizer manufacturers clearly mention the name and concentration of alcohol on the bottle, but some do not mention the concentration and name of the alcohol. Many commercial samples of hand sanitizers were analyzed qualitatively & quantitatively by the newly developed ^{1}H NMR based method in order to check the compliance of these samples w.r.t WHO guidelines. It was found that one locally procured sample contains toxic methanol (~ 71%) while others contains much lesser amount of isopropyl alcohol (~33%). It was also found that approximately 60 % commercial samples analyzed by this method do not meet WHO guidelines. IOCL has come up with “IOC Clean”, an ethyl alcohol based hand rub solution to sanitize hands in a bid to strengthen efforts to fight the coronavirus.

Synthesis, Characterization and Applications of Highly Reactive Polyisobutylene

Tota Rajasekhar, Gurmeet Singh, Anju Chopra
Research & Development Centre, Indian Oil Corporation Ltd., Sector-13, Faridabad, Haryana – 121007, India
Presenting author, E-mail: rajasekhart@indianoil.in;

Fuel and oil additive industry in general use polyisobutylene based dispersants, due to their exclusive properties of cleaner burning, high shear stability, tackiness, water and oxidation resistance, and cohesive strength. Furthermore, PIB based dispersants possess a variety of other value-added advantage including less char formation at high temperature performance conditions and ability to improve final lubricant and fuel performance. Low molecular weight highly reactive polyisobutylene (HR-PIB) is a vital precursor in the preparation of polyisobutenylsuccinimides, which are used as motor oil and fuel additives. The widely used traditional process to prepare HR-PIB is based on boron trifluoride catalyst system. The traditional process utilizes an alcohol or ether nucleophile at temperatures below -30°C. The requirement of low temperatures and highly purified feed make the process expensive. Recently, researchers studied metal halide complexes; however, their poor solubility in the preferred nonpolar solvents imposed a serious limitation for industrial application.

Authors have developed a fully hydrocarbon soluble catalyst that produce HR-PIB with quantitative yields, ~95 % and up to 85% exo-olefin end-functionality at 0-10°C. We have investigated effect of temperature, method of catalyst dosage, catalyst to additive ratio, catalyst concentration, etc., as the part of process development enabling HR-PIB suitable for post-polymerization modification.

Estimation of Ethers Generated Through Conversion Of Lower Branched Olefins In Light Cut Naphtha (LCN) using GC-MS and NMR Technique

Dheer Singh*, Ravindra Kumar, S. Saravanan, Anju Chopra, J. Christopher, G. S. Kapur and S.S.V. Ramakumar
Indian Oil Corporation Limited, Research and Development Centre, Sector-13, Faridabad, Haryana (India)
Email: singhdheer@indianoil.in;

In the etherification process, C5/C6 iso-olefin presents in light cut naphtha (LCN) react with methanol in the presence of acid catalyst to produce C5+ ethers which have high octane number. These lower molecular weight unsymmetrical ethers, such as methyl t-butyl ether (MTBE) and t-amyl methyl ether (TAME) can be added to C5 -C10 hydrocarbon-containing gasoline products to increase gasoline octane performance without the addition of deleterious components such as tetraethyl lead and benzene. GC coupled with mass spectrometry (GC-MS).method was developed for monitoring the etherification process by characterizing the products completely and correlated the components with NMR method.

Since light cut naphtha is a mixture of C2 - C6 olefins, monitoring of selectively conversion of C5 olefins (isoamylenes) to tert-amyl methyl ether (TAME) and branched ethers in the presence of other hydrocarbons is very difficult. Therefore, a separation scheme using appropriate capillary column was devised to separate TAME, MTBE and other ethers generated during the etherification process in the presence of olefin isomers. The depletion of isoamylenes in light cut naphtha (LCN) feed and corresponding product was also monitored using GC-MS technique. The generated ethers were identified by Mass Spectrometry (MS) using NIST library and quantification was done using the internal standard method. The data obtained for total ether content (TAME and MTBE) was validated with NMR technique. A good correlation was found between GC and NMR spectral results (correlation coefficient R^2 = 0.995).

Keywords: Gas chromatography, Mass spectrometry, NMR, Etherification, Isoamylenes.

Quick and Simultaneous Estimation of Oxygenates, Octane Booster, Hydrogen Content and Hydrocarbon Types in High Octane Gasoline by q-^{1}H NMR Spectroscopy

Sujit Mondal*, Emmandi Ramu, Ravindra Kumar, J. Christopher, Gurpreet S. Kapur & SSV Ramakumar
Indian Oil Corporation Limited, R&D Center, Sector-13, Faridabad-121007
*Corresponding author: mondals3@indianoil.in

Fuels with higher octane rating are considered more premium as they have better resistance to knocking. Standard gasoline has an octane rating of 91 which is being used for most standard vehicles. However with high performance luxury vehicles, it is advisable to use fuels with higher octane ratings to ensure better health of the engines. Additionally in order to mitigate harmful emissions and to meet environmental considerations use of high octane gasoline is known to be more effective. Towards that end premium quality gasoline with greater than 99 octane rating is being promoted by OMCs throughout the country. Blending of suitable oxygenates and octane boosters to BS-VI gasoline are done to formulate these premium quality fuels. Estimation of various parameters, like % of oxygenates, octane booster, hydrogen content as well as hydrocarbon types, such and aromatics, olefins are imperative for the formulation of such products. Oxygenate such as ethanol, methanol and hydrocarbon types [Paraffin, olefin, naphthene and aromatic (PONA)] can be estimated by standard GC methods. Estimation of octane booster by GC has been found to be challenging as poor peak separation characteristic for octane booster was observed. Moreover standard GC method may not be applicable for PONA analysis as the presence of octane booster may affect overall estimation. Estimation of oxygenates and octane booster can be done by IR. However simultaneous estimation of all the above mentioned parameter cannot be done by any such technique. Herein we report a new quantitative ^{1}H NMR based method for the estimation of oxygenate , octane booster, hydrogen content as well as PONA in high octane gasoline. The method uses Hexamethyldisiloxane (HMDSO) as the internal quantitative reference standard with respect to which the % age of oxygenates, octane booster, hydrogen content, H/C and O/C ratio have been estimated. Application of the principal group molecular weight (GMWt) on the same spectrum provides the PONA analysis. Results of the study along with comparable data for oxygenate and octane booster obtained by IR analysis will be presented.

Keywords: Quantitative ^{1}H-NMR spectroscopy, High Octane Gasoline, Octane Booster, PONA.

OP-7

Facile synthesis of PANI/SnO2 and PANI/SnO_2 /rGO ternary composites for high performance chemi-resistive gas sensors applications

P. Senthil
Department of Chemistry
Mohamed Sathak Polytechnic College, Kilakarai.Tamilnadu, India PIN 623806
Email: kpssenthilji82@gmail.com

PANI/SnO_2 and PANI/SnO_2/rGO ternary composites have been synthesized by by facile one step hydrothermal approach and followed by polymerization method. To explore the structural, optical, morphological and elemental composition of the composites, it has been characterized by XRD,TEM, EDAX, FTIR and EPR techniques. XRD indicates that the tetragonal rutile phase with the with nanocrystallite size range from 25-35 nm. The N_2 adsorption-desorption measurement showed that ternary PANI/SnO_2/rGO composite showed huge specific surface area (114.51 m^2/g) and pore size (17-21 nm), which is higher than the bare SnO_2 (surface area=83.51 m^2/g; pore size=33-37 nm).The chemiresistive type gas sensor was fabricated and the gas sensing properties of designed sensors were examined towards different gases (ethanol, methanol, carbon monoxide, oxygen, H_2S and NH_3). The results exposed that that ternary PANI/SnO_2/rGO showed better sensor sensitivity. It showshigh sensing response (56 %), fast response (35 s) and recovery time (40 s) towards H_2S gas than other gases. The improved gas sensing mechanism was also proposed.

OP-8

Ability of Numerous Recent Chemical and Physical approaches for the Elimination of Wastewater Dye

Sapna Tomar , Nitika Tomar
Department of Applied Sciences and Humanities (Chemistry)
Email: sapnatomar_rbs@rediffmail.com , nitikakuss@gmail.com

Dye effluents emitted from a variety of dye-use industries are toxic to the atmosphere and to living things. As a consequence, the presence of dye effluent in environmental water sources is becoming an increasing issue. Environmentalists and the civilian community a long-term sustainable and effective method of treatment of dye effluents should be developed to resolve this problem. Until publication, dye wastewater should be processed first to mitigate the negative waste water impacts on the atmosphere and on living organisms. However, due to a lack of knowledge on efficient dye removal methods, it is difficult to settle on a single technique to address the prevailing dye effluent problem. Accordingly, this paper examines current study papers on different molecular, chemical and physical dye removal approaches in order to find their effectiveness by a percentage of dye removal. While there are several tried and tested current and the methods evaluated for the removal of pigment, most of which have a common drawback in the production of secondary emissions to the atmosphere. This paper illustrates, adsorption (physical) dye removal is considered as one of the most effective dye removal techniques. This paper also recommends the use of a mixed adsorbent, since it is envisaged that this approach would be more effective and would be able to extract dyes at a quicker rate.

Keywords: Dye effluents, wastewater, adsorbent,chemical and physical method

OP-9

Chemical Recycling of Waste Plastic into Hydrocarbon Oil via Pyrolysis

Bineesh Vijayan K, Gurmeet Singh, Anju Chopra
Research & Development Centre, Indian Oil Corporation Ltd., Sector-13, Faridabad, Haryana – 121007, India
E-mail: kvbineesh@indianoil.in

Plastic in modern society make an important contribution to all major daily activities and their global production and utilization has grown rapidly over the last few decades. Plastic are highly durable, versatile, light weight, do not rust and low production cost, which makes them ideal choice for wide varieties of applications in industry as well as in domestic areas. Due to the increased use of plastics, the waste generated from their production, transportation and consumption has created various environmental problems. Plastics, designed to be resistant to biological degradation, remain in the ecosystem for many years. The huge and ever increasing amount of plastic waste is thus a burning issue throughout the globe, as nature cannot handle it. Management of waste plastic through sustainable recycling routes is need of the hour.

The present study describes the value addition of various waste polyolefins like high density polyolefins (HDPE), linear low density polyolefins (LLDPE), polypropylene (PP) into valuable hydrocarbon oils via catalytic pyrolysis process. The yield and nature of the product was found to vary with feed and the catalyst. The major portion of the liquid product is in the range of C6-C16.The obtained liquid product is free from sulfur compounds.

OP-10

Bioprospecting of Alkaliphilic Nesterenkonia Lacusekhoensis In Decolorization of Azo Dye For Its Application In Treatment of Highly Alkaline Textile Effluent

Amrik Bhattacharya, Nidhi Goyal, Anshu Gupta*
University School of Environment Management, Guru Gobind Singh Indraprastha University,
Sector 16-C, Dwarka, New Delhi-110078, India
* anshugupta@ipu.ac.in

Azo dyes are one of the recalcitrant organic pollutants known to have diverse toxic effects on the environment, thus its remediation from the environment using sustainable mean is of utmost necessity. The severity of the pollutant further aggravates if it is present in an alkaline environment like in textile-originated wastewater. To remediate dye from this alkaline system, there is a requirement for dye degrading alkaliphilic microbes. In the present study, potential azo-dye methyl red (MR) decolorizing microbial strains were isolated from the alkaline textile effluent (pH 13). Among four isolated strains, Nesterenkonia lacusekhoensis EMLA3, found to grow at alkaline pH (pH 11.5) and simultaneously remediate high level (200 mgL^{-1}) of MR from alkaline medium was selected for detailed studies. Interestingly, dye decolorization was also observed in presence of high salinity levels (20-120 gL^{-1} NaCl). Formation of low molecular weight metabolites identified through GC-MS studies inferred biodegradation to be responsible for dye decolorization. The strain was also applied for treatment of real textile effluent having high alkaline pH and salinity, wherein efficient decolorization of effluent after 96 h of treatment was successfully attained. The merit of the bacterium is that the initial pH (13) of the effluent got reduced to 8.6 after the treatment along with COD reduction. Thus N. lacusekhoensis EMLA3 could be effectively used for bioremediation of dye-containing textile effluents.

Keywords: Nesterenkonia lacusekhoensis EMLA3; alkaline pH; Azo dye; Methyl red; textile effluent; Bioremediation.

OP-11

Thiol-tethered Nanocomposites as Future Materials

Kalpana Chauhan
Department of Chemistry, School of Engineering and Technology, Central University of Haryana, Mahendragarh-123031, India
*kalpana13chauhan@gmail.com; kalpanachauhan@cuh.ac.in

Thiol is an important group and is present widely in natural products. Also, the strong chelating property of thiol is used to treat poisoning by heavy metals. Therefore, herein we developed a process for thiomers from polysaccharide via an innovative green approach using innocuous low- cost thiourea reagent. Subsequently, the synthesized thiomer were used as reducing agents to synthesize nanocomposites. The detailed structural characterization results supported the uniformity of modification, which ultimately resulted good control for the size and shape in nanocomposites. The controlled size and shape are important in nanocomposites for exception capabilities in applications. Rather, the synthesized nano-composited confirmed exception results for heavy metal ions and in antimicrobial applications. Overall the applied protocols are simple, green and less-energy intensive, and which also have scale up potential. Also, the materials have prospective to be an alternative to the conventional materials.

Keywords: Thiomer, Nano-composites, Heavy-metals, Antimicrobial

OP-12

Comparative Study of Poly(acrylate-co-maleic anhydride)amides of Hindered Phenolic Schiff Base Amine For Lubricant Applications

Ekta Faujdar,* Raj K. Singh
Advanced Crude Oil Research Centre, Analytical Sciences Division, CSIR-Indian Institute of Petroleum, Dehradun-248005, Uttarakhand
ektafaujdar15@gmail.com

Automobile industries require a significant amount of lubricants, especially the engine oil, and comprise up to half of the total lubricant demand. The foremost aim of the lubricant is to prolong the engine's service life under harsh operating conditions. Several specialty additives have been used in the base oil to improve the engine oil's effectiveness and efficiency. A finished lubricant performs several critical functions, including oxidation inhibition, cleaning, suspending the generated sludge, protection from corrosion, and high friction due to metallic surface asperities. Two essential properties of a lubricant are; good low-temperature property and good high viscosity index, i.e., minimum variation in viscosity with varying temperature, which is generally incorporated by blending the viscosity index improvers and pour point depressants. It is a matter of great concern if an efficient multifunctional additive could be developed possessing these important characteristics. In view of this, four poly(acrylate-co-maleic anhydride)amides of hindered phenolic Schiff base amine were synthesized, having varying alkyl chains. The molecular characterization was done using various spectroscopic techniques. A comparative performance study of these synthesized additives was done in polyol reference base oil to investigate the effect of long alkyl chain on VI, pour point depressant, detergent-dispersant, and anti-oxidant additive properties. Poly(acrylate-co-maleic anhydride)amides of the C18 alkyl chain showed the best results enhancing the viscosity index of base oil from 178 to 195 at 5000 ppm additive dose. A maximum oxidation inhibition of 41 % and a significant enhancement of 35 % in detergency/dispersancy was observed at this dose.

OP-13

Catalytic Intervention for Tailoring Gasoline Composition for Octane Barrel Improvement

M. Kadgaonkar, V. Chidambaram, A.V. Karthikeyani, A. C. Pulikottil, M. Sau, G. S. Kapur, S.S.V. Ramakumar
Indian Oil Research & Development Centre, Sector-13, Faridabad, India
kadgaonkarm@indianoil.in

Fluid Catalytic Cracking (FCC) process is a major secondary refining operation that caters approximately 40-50 % of total gasoline pool. ZSM-5 catalyst additive finds widespread usage in a FCCU for both light olefin production and gasoline octane improvement. Conventional ZSM-5 system cracks gasoline to LPG and propylene components and consequently leads to lower gasoline yields. However, with increased demand for gasoline, refiners prefer to enhance olefin yield without or minimum loss of gasoline.

To increase octane number/octane barrel with minimum loss of gasoline yields tailoring of catalyst to generate selective hydrocarbon composition with enhanced octane contributing molecule is required. A customized catalyst additive formulation with tailored zeolite system having enhanced selectivity to high octane molecule and an active matrix component to crack heavier fraction is discussed.

This additive prepared using similar procedure reported in US Pat. No. US 75718271B22009 & IN 201921040347 is characterized for different physico-chemical properties such as Apparent Bulk Density (ABD), Attrition Index (AI), X-ray Diffraction (XRD), Surface Area (SA) and Particle Size Distribution. Performance of tailored additive prepared at lab and commercial scale evaluated in ACE R+ unit is discussed in the paper along with its commercial plant trial performance in a commercial FCC unit.

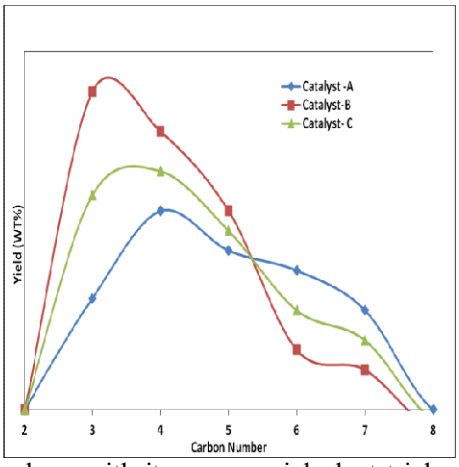

Fig.1: Shift of molecular compositional distribution with catalyst (Catalyst- A= FCC Catalyst (Zeolite Y Based), Catalyst- B= FCC Catalyst + Conventional ZSM-5 Catalyst, Catalyst- C= FCC Catalyst + Tailored Catalyst)

Xrf-Xrd Analysis of Turbine Deposits: Problems And Solutions

Vibhav Pandey*, Rashmi Bagai, Jayaraj Christopher and Gurpreet S Kapur
R&D Centre, Indian Oil Corporation, Sector-13, Faridabad-121006, India
pandeyv2@indianoil.in

Steam turbines are commonly used to convert the heat energy of steam to finally generate electricity, propulsion for ships, airplane etc. There may be series of specially designed blades inside turbine which capture the steam and a rotational force is generated. In general, steam from a water boiler is pressurized into turbine which propels spinning motion of turbine blades. During operations, various materials may deposit on the turbine blades and affect the efficiency of turbine. Deposits on turbine blades may restrict steam flow, corrode the turbine blades and cause imbalance in motion of turbine blades in addition to reduction of turbine efficiency and MW generating capacity, and malfunction of valves and seals.

The determination of elemental and phase composition of these deposits is important for prevention of deposit formation on the blades and also for cleaning of deposits on the blades. In this study, deposit samples on turbine blades from IOCL refinery have been characterized using X-ray diffraction (XRD) and X-ray fluorescence spectroscopy (XRF). Elemental analysis of deposit samples by XRF shows presence of Si, Na, Cl as major elements which appear in different phase composition including Silica, Sodium silicate, Sodium carbonate, Sodium chloride etc as indicated by XRD. It takes only few hours of a chemical upset such as leak or boiler carryover to build up deposits on the turbine blades, but it takes thousands of hours of operation with pure steam to remove these deposits. In this regard, techniques such as XRD and XRF have proved to be vital analytical tools for understanding root cause of deposits on the turbine blades. Based on the data, source of these contaminates can be traced and preventive measure can be taken to avoid shut down and to identify suitable reagent to clean these deposits.

Keywords : Turbine deposit, Elemental composition, Phase analysis, XRF, XRD

OP-15

Toxic Effect And Risk of Disease Among Nail Artists of Bhopal, Due To Toxic Trio – Toluene, Dibutyl Pthalate And Formaldehyde.

Pinki Sharma and L K Tiwary
PGT, Barkatullah University, India,
Professor, Barkatullah University, India
mailtosharmapinki@gmail.com

Modern day nail polishes have the formulations, which contains highly toxic chemicals toluene, dibutyl pthalate and formaldehyde. These products affect the health of workers engaged in saloon, particularly in nail salons. Workers breathe in harmful vapors, dusts and mists, and are exposed to those products on skin and eyes, or even sallow sometimes accidently through food. This exposure is intensified on the use of varieties of other nail products during their longer duration of work. Acetone contains leads to headache, dizziness, and irritation to eyes, skin and throat, causing various breathing problems.

- Long term exposure to dibutyl phthalate causes nausea and irritation to eyes, skin and throat.
- Formaldehyde causes difficulty in breathing including coughing, asthma like attacks, wheezing, it can also cause cancer on prolonged exposure.
- Toluene makes skin dry, causes headache and dizziness, irritation to eyes and nose.

The present study aims to investigate the toxic effects of above potentially hazardous chemicals on health of nail artists of Bhopal and investigates the impact of long term exposure of various nail products on the nail artists. It has been found that these workers developed, the symptoms of nausea, breathlessness and asthmatic problems, on continuous exposure to these toxic chemicals.

After a survey of two months and after detailed study on this problem, some preventive measures have been suggested to reduce the hazardousness of this problem.

The measure suggestion include, absorption spill of nail products and scrubbing the area with detergents. Proper ventilation of working area, use of safety glass, gloves and aprons. The suggestion, was found to be effective, when adopted by concerned nail artists.

*CR Patra, E-mail: crpatra@iict.res.in;

Environmental and industrial heavy metal (arsenic, lead, cadmium etc.) pollution is one of the major reasons for humans to become susceptible to various health hazards. Cadmium (Cd) is a common heavy metal among all that causes major environmental pollution with adverse effects on the human health and functioning. The fundamental mechanism of Cd induced vascular toxicity is through inhibiting angiogenesis via reduction of nitric oxide (NO) bioavailability and induction of apoptosis. Several approaches were attempted to treat Cd-induced toxicity such as the use of anti-oxidants and chelating agents. However, these approaches are associated with their own limitations. In this context, there is a critical need for the development of alternate treatment strategies to address the Cd intoxication. One such novel approach is therapeutic angiogenesis which could be an ideal option to recover from the toxicity. Our group already demonstrated the biocompatible europium hydroxide nanorods (EHN) which exhibited excellent pro-angiogenic properties through enhancement of intracellular nitric oxide (NO). In the present study, we have evaluated the effect of EHN on Cd induced toxicity in EA.hy926 (hybrid endothelial cell line) using various in vitro and in vivo assays. EHN improved the viability of EA.hy926 cells pretreated with Cd, reduced apoptotic cell population, increased NO production and promoted blood vasculature development in chick embryo model. Down-regulation of p53 and up-regulation of Bcl-XL along with enhancement of NO was found to be the plausible molecular mechanisms underlying the retrieval of Cd induced vascular toxicity by EHN. Henceforward, we strongly hope that the EHN could be developed as potential alternative therapeutic nanoparticle for overcoming Cd induced toxicity and associated diseases.

Antifungal Activity of New Series of Some Synthesized Pyrimidine Derivatives

N. Verma and D. N. Singh*
Department of Chemistry, K. S. Saket PG College, Dr. R.M.L. Avadh University Ayodhya-224001, India.
nvermasaket@yahoo.co.in

Pyrimidine pharmacophore is an important and integral part of nucleic acid and play an essential role in several biological processes and occupy an important place in the therapeutic area. Pyrimidines derivatives were found to possess a wide range of diverse activities such as anti-inflammatory and analgesic, antimicrobial, anti-avian influenza virus (H5N1), against herpes simplex virus type-1 (HSV-1) and hepatitis-A virus (HAV), serotonin 5-HT6 receptor antagonist, anti-arrhythmic agents. Pyrimidine analogs have been already demonstrated as platelet aggregation inhibitors, antagonists, anti-conceptive and antiparkinsonism agents. The pyrimidine core is a structural constituent of critically important drugs like fluorouracil, etravirine, risperidone, iclaprim, avanafil, and rosuvastatin. Keeping in view the importance of pyrimidine ring in various therapeutic agents and our continuous work to design and synthesis of novel pyrimidines based new chemical entities of biological significance, recently, we have designed and synthesized the new series of multifunctionalised halogenated pyrimidines and their antimicotic activities were evaluated in vitro against five human pahtopathogenic fungi using ketoconazole as standard reference. In this presentation, the detailed synthetic procedure, biological screening profiles and characterizations of the synthesized compounds by their spectral data (^{1}H NMR, ^{13}C NMR, EIMS, UV and IR) analysis will be discussed.

Future Aspects of Flame-Retardant Polyurethanes

Takashiro Akitsu
Department of Chemistry, Faculty of Science, Tokyo University of Science, Japan
E-mail: aktisu2@rs.tus.ac.jp

Indeed, as I have studied on retardant compounds for polymers as collaboration works with Indian university [1-4],"Materials and Chemistry of Flame-Retardant Polyurethanes" may be one of the important remand from the viewpoint of social safety of fire accidents.

In 2017, for example, a fire broke out from a three-story building in Yoyogi 5-chome, Shibuya-ku, Tokyo, and burned to the roof of the second car of the regular train (8-car train) from Honatsugi to Shinjuku that stopped between Sangubashi and Yoyogi-Hachiman on the Odakyu Odawara Line. According to the Tokyo Fire Department and Odakyu Electric Railway, about 300 passengers got off the railroad tracks and evacuated, and no one was injured. The roof of train (Figure) was made of polyurethane materials.

In this talk, I will briefly review characteristic of polyurethane and known features of its retardant, and I will discuss expected fire considering "Future Aspects" such as low concentration of oxygen and non-gravity conditions assuming marine or space life of human being.

*chemshiva@gmail.com

Cadmium sulfide (CdS) quantum dots (QDs) were prepared by chemical precipitation method by using β-cyclodextrin as reducing agent. Optical property of CdS is investigated using ultra violet visible-diffused reflectance spectroscopy and photoluminescencespectroscopy. The absorption band edge emission of this particle was 469 nm which is considerably blue shifted compared to those of the bulk CdS. The calculated band gap of CdS quantum dot is 2.62 eV showed a difference of 0.2 eV energy greater than that of bulk, indicating quantum size effect. The formation of CdS quantum dots were confirmed by the structural characterization using XRD. The synthesized quantum dot has size in the range of 3.5nm with zinc blende crystallite structure. The morphology and molecular confirmation were studied using SEM and FTIR. The different magnification of SEM images clearly indicates the formation of plates like nanocluster. Photocatalysis based on semiconductor quantum dots, which utilize the solar energy can be used for the elimination of pollutants from aqueous media and applied for water purification. The photocatalytic activity of cadmium sulfide quantum dot was tested for degradation of rhodamine B dye under solar light. Effect of weight of catalyst, concentration of dye, pH of solution and reusability of catalyst were investigated. Existence of isosbestic point observation of high intense absorbance peak at 550 nm at 300 min in different matrix circumstances confirms the formation of leuco Rh B.

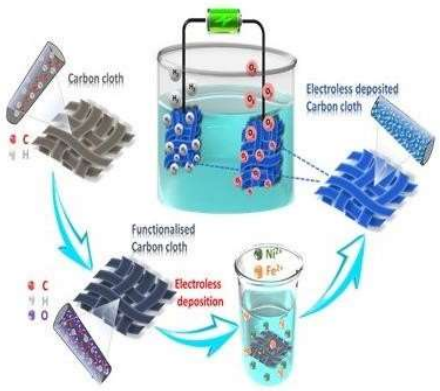
Keywords: Cadmium sulphidequantum dots, β-cyclodextrin, photocatalysis, Rhodamine B, solar light

OP-21

A greener approach towards fabrication of flexible carbon cloth electrode for water splitting

Alankar Kafle, Tharamani C.N.*
Department of Chemistry, Indian Institute of Technology Ropar, Punjab-140001, India
2018cyz0014@iitrpr.ac.in , tharamani@iitrpr.ac.in

Development of cost-effective electrodes for efficient electrochemical water splitting with industrial applicability is of great importance. Mostly electrodes are fabricated by powder casting on a rigid substrate with insulating binder impeding the ion transport and hence lowering the overall efficiency. In that respect, self-standing binder-free electrodes are an innovative approach possessing an increased density of exposed active sites to accomplish faster mass transport, providing excellent adhesion between catalyst and substrate. Self- supported carbon cloth based flexible electrodes has advantages of high activity, light weight and eco-friendly nature favouring industrial applications. Electroless deposition is most probably the simplest approach for electrode preparation, but still underexplored due to use of expensive sensitizer and activator. Herein, we manifested a cost-effective and greener approach to design self-supported flexible electrode depositing NiFeS and NiFeP over carbon cloth by proficient electroless deposition, eliminating traditionally expensive sensitizer and activator. As prepared, NiFeS@OCC and NiFeP@OCC demonstrate good bifunctional activity and require a low overpotential of 220 & 270 mV during OER, 223 & 300 mV during HER to reach 10 mA cm^{-2} which are comparable to that of state of art catalyst. The promising bifunctional activity and stability of these flexible



electrodes under full cell conditions for overall water splitting signify great potential for their practical implementation in industries.

Effect of transition metal oxide dopant on corrosion protecting behavior of polypyrrole

Monika, Gita Rani
Department of Chemistry, Chaudhary Devi Lal University, Sirsa - 125055, Haryana, India
gtcdlu@gmail.com

Conducting polymers are the organic polymersand various applications of conducting polymers can be increased by doping with other functional materials to form polymer composites. Here, in present research work, effect of doping of titanium dioxide has been studied on corrosion protecting behavior of polypyrrole.

Polypyrrole and polypyrrole composites of titanium dioxide of 5%, 10% concentrations are electropolymerized on the surface of stainless steel by cyclic voltammetry technique. The corrosion protecting behavior of polypyrrole and polypyrrole-titanium dioxide composites of different concentrations in 1M HCl was evaluated by Electrochemical impedance spectroscopy (EIS) and potentiodynamic polarization techniques. From the EIS measurement, it is observed that the charge transfer resistance (Rct) value i.e. reactions intensity at coating/metal interface of Polypyrrole-TiO_2compositesof different concentrations is higher than pure polypyrrole. The double layer capacitance (Cdl) of all composites is lower than pure polypyrrole. So corrosion protection efficiency of Polypyrrole-TiO_2 of different concentrations are better than pure polypyrrole on stainless steel surface. The higher values of Rct for Polypyrrole-TiO_2 composites can be explained by the building up of a primary protective passive layer. From the polarization analysis, it was observed that pure polypyrrole coated steel possessed a lower Ecorr and higher Icorr value than polypyrrole-TiO_2 composites which indicated that polypyrrole composites give better corrosion protection on the stainless steel surface.From the EIS and polarization analysis, it was confirmed that polypyrrole-TiO_2 composites give better corrosion protection on stainless steel surface than pure polypyrrole coating.

Chicken Eggshell as Low-cost Calcium Source in the Synthesis of Bioactive Glass and Glass-ceramics

Sujan Kumar Chakrabarti[1], Sudip Kumar Das[2]*
Department of Chemical Engineering, University of Calcutta, 92 APC Road, Kolkata - 700009, India
* skdchemengg@caluniv.ac.in

Bioactive glass ceramics have come up as an important class of biomaterials. Many products based on these biomaterials have found extensive use in biomedical applications - bone implant and bone graft, drug delivery, tissue engineering, etc. are some examples and many new applications are coming up [1-3]. Bioactive glasses are primarily composed of a three dimensional silica network with other compounds incorporated in the structure. One of the primary constituents is calcium oxide (CaO) and it is used in most of the commercial bioactive glass and glass ceramics products. Composition of CaO can range from 10 to 45 wt % and in glass manufacture commercial $CaCO_3$ is primarily used as the source for CaO. Chicken eggshell, which is generated worldwide in huge quantities as solid waste, contains ~ 88% of CaO. Although some of it is used in agriculture, even in the developed countries some 30% is still discarded [5,6]. This can be utilized as an economical source of CaO in glass composition. The present work examines the suitability of chicken eggshell as the candidate for calcium source in the composition of bioactive glass. Three glass samples were synthesised – all having the 45S5 Bioglass® composition (45% SiO_2, 24.5% CaO, 24.5% Na_2O and 6.0% P_2O_5, all in wt%). Three separate calcium sources – commercial $CaCO_3$ powder for glass 1, CaO powder derived from eggshell for glass 2 and powdered raw eggshell for glass 3. Chicken eggshells were cleaned and then calcined at 900°C for 3 hours for obtaining CaO powder. The 3 glasses had bulk densities of 2.460, 2.316 and 2.515. FTIR spectra of the glasses showed the characteristic Si-O-Si glass network and the XRD data showed the amorphous nature of all 3 glass samples. Vickers Hardness (5 measurements average) of the 3 glasses was 5.074 GPa, 5.536 GPa and 5.746 GPa, respectively, showing the similar mechanical strengths for the glasses. The in-vitro bioactivity of the 3 glasses was tested by soaking in SBF solution for 7 days and then performing SEM, FTIR and XRD studies to confirm the formation of surface hydroxyapatite layer. Very good bioactivity was exhibited by all the glass samples. Toxicity assessment was done by using chicken red blood cells which confirmed that all glass samples were non-toxic in nature. So, CaO obtained from chicken eggshell and raw eggshell itself can be considered as economical alternative calcium source for bioactive glass and glass ceramics manufacture.

Poster Presentation

A novel method of nitriding of steel (AISI-SAE 52xx) using melamine derived from urea

Prabal Dasgupta [1], Femi Olu Emmanuel [2] and Elias Tadesse [2]

[1] IACS Kolkata (Retired) [2] Jimma University, Facuty of Material Science and Engineering Jimma , Ethiopia

E-mail: pg23091952@gmail.com

Urea on heating under normal pressure yield melamine at about 275 degree Celsius and reaches equilibrim at about 325 degree Celsius[1] in 6 hours according to the chemical reaction

$$6NH_2CONH_2=(NH_2CN)_3(\text{melamine})+6NH_3+3CO_2 \quad \ldots\ldots\ldots\ldots\ldots\ldots (1)$$

Along with biurate, cyanuric acid and water insoluble intermediates but yield of melamine is 99.4%.

Melamine, on the other hand, is widely used as a fire retardant due to the fact that at an elevated temperature (above 500 deg Cel) it produces nitrogen gas.

We have made use of this chemical reactions to nitride medium carbon steel (AiSI-SAE:52xx) sample and nitrided samples are characterized by powder XRD, metallurgical microscopy and scanning electron microscopy. TheVicker hardness of the steel samples in creased manifold.Extent of corrosion resistace power, particularly in saline condition, was further enhanced as evidenced from cyclic voltammogram of nitrided and un-nitrided steelsamples.

Defluoridation of ground water by chemically modified maize husk as an adsorbent

Pravinkumar and Anurag Choudhary*
Assistant Professor, Department of Chemistry,
JNV University, Jodhpur
anurag051981@gmail.com

The defluoridation of ground water concerned one of most noticeable attention among the world community. The present investigation deals with effective removal of toxicants presents in ground water using bio adsorbents from agricultural waste. Research has been probed for successful removal of fluoride ions by chemically modified maize husk as adsorbents. Fluoride containing ground water samples were collected from Gadra road region of Thar desert of Rajasthan. Batch experiments were conducted to establish the optimal conditions like pH, dose of the adsorbent, and contact time. The prepared biosorbents were applied on these collected samples under optimized conditions and found to be effective with removal efficiency ranging from 79 to 83 %. The adsorption process obeyed Langmuir adsorptionmodel.

Hyperbranched polymers (HBPs) or dendrimers have been used as additives for thermoplastics. Incorporation of HBPs or dendrimers in commodity thermoplastics, such as, polypropylene (PP) have proven to increase its toughening properties, nucleating efficiency, processability etc. Here, we report Polyethyleneimine (PEI), a hyperbranched polymer as a nucleating agent for PP in the presence of a compatibilizer - maleic anhydride grafted polypropylene (PP-g-MA). The compatibilized PP-PEI blends displayed significant improvement in the crystallization behaviour as well as mechanical and morphological properties as compared to the non-compatibilized blends. Decrease in crystallization time for PP/PP-g-MA/PEI blends was further confirmed by isothermal (Avrami analysis) and non-isothermal crystallization kinetics (through Jeziorni as well as Mo models). In addition, PP-PEI blends were examined for their ability to capture carbon dioxide (CO_2) through thermogravimetric analysis (TGA). PEI contains primary and secondary amine groups that can chemically react with carbon dioxide. In this case also, compatibilized blends showed remarkable increase in CO_2 absorption efficiency as compared to the non-compatibilized blends.

Lab Scale MEC Determination of Fire Supression Agents

Chandra Prakash, Durgesh Nandini, Ashish Kumar, I. P.Singh, R. K. Tanwar
Centre for Fire, Explosive and Environment Safety (CFEES), Defence Research and Development Organisation (DRDO), Timarpur, Delhi-110054, India
chanderprakash@cfees.drdo.in

Minimum Extinguishing Concentration (MEC) of gaseous or liquid fire extinguishing agents is the measurement of their fire extinguishing capability to extinguish flammable and combustible fuel fire. It is an important parameter to calculate design concentration of fire suppression agent for their fire protection system development. The Cup-burner test method has been established as standard method for MEC determination of fire suppression agents. This study investigated the lab scale method for MEC determination of newly developed fire suppression agents and their screening for futuristic applications as in-kind halon alternatives. This experimental tool consists of specifically designed Combustion tube having provision for introduction of air/agent mixture in upper part and properly fitted methane/hydrogen fuel burner in lower part. Flame Ionization Detector has been used for flame extinguishment detection. The MEC value of Halon 1301 and newly developed perfluorinated liquid fire suppressing agents were determined using very small quantity (approx. 1-3g). The experimental results were found in good agreement i.e. exhibited good reproducibility and repeatability based on average of five replicate experimental determinations.

PP-5

Impact of Biojet Blending on Jet A1 Fuel Properties

Fariha Saleem *, Krishnarao Lopinti M. Chakradhar, A. K. Arora, V. Kagdiyal, Deepak Saxena
Indian Oil Corporation, Research & Development Centre, Faridabad-121007
* saleemf rishnaraol@indianoil.in

Aviation turbine fuel (ATF), kerosene type, Jet A-1 fuel consists of predominantly refined hydrocarbon derived from conventional sources such as crude oil, natural gas liquid condensates, heavy oil, oil shale and oil sands. The use of laboratory synthesized hydrocarbons from renewable new sources is beyond the scope of conventional ATF, kerosene type Jet A1 fuel specification. However, usage of synthesized fuel components from renewable sources is envisaged to decrease carbon footprints.

The stringent specifications of ATF are aligned with international aviation fuel standards like British Ministry of Defense Specification DEF STAN 91-091 and ASTM 1655 specification to meet the ATF quality standards and facilitate aircraft refueling in different countries. The ASTM specifications (D7566) is designed for using biojet fuels derived from renewable source in Jet A1 fuels which is in line with international specifications. Bureau of Indian Standard (BIS) has also issued later specification IS 17081: 2019 for use of biojet fuel components from renewable sources in Jet A1 fuel.

Biojet fuels can be blended with conventional Jet A1 fuel according to ASTM D7566 or IS 17081 specifications limits and biojet blended Jet A1 fuel has to meet IS 1571 specifications also. A study was carried out by using two different types of biojet fuels i.e. SPK-HEFAs (Synthesized paraffinic kerosene derived from hydrogenation and deoxygenation of fatty acid esters and free fatty acids) and ATJ-SPK (hydro-processed synthesized paraffinic kerosene derived from ethanol or isobutanol) and blended in conventional Jet A1 fuel at different ratios. The properties of biojet-Jet A1 blends significantly influenced are sulfur content, lubricity and aromatics. Detail impact on properties of biojet-Jet A1 blends vis-a-vis properties of jet A1 fuel as per specifications will be discussed in the full paper.

Key words: Biojet, FT-SPK and ATJ-SPK, thermal stability, Jet A1 fuel

Doping engineering through Vanadium and Nitrogen dopent in MoS_2 enhance the catalytic performance towards HER in acidic and alkaline medium

Saikat Bolar[a,b], Subhasis Shit[a,b], Tapas Kuila[a,b]
[a]Surface Engineering & Tribology Division, Council of Scientific and Industrial Research-Central Mechanical Engineering Research Institute, Durgapur - 713209, India
[b]Academy of Scientific and Innovative Research (AcSIR), CSIR-CMERI Campus, Durgapur - 713209, India
E-mail: tkuila@gmail.com

With the growing civilization the eager of fossil fuels are increasing gradually. Hydrogen energy is come out to be sustainable and never ending energy source to resolve the energy crises. Hydrogen has highest gravimetric energy density (120 kJg^{-1}) than all the other conventional energy resources[1]. Hydrogen evolution reaction (HER) through electrocatalytic pathway is emerging as contemporary green technology to combat with the modern energy crises scenario. In this connection, selection of suitable electrocatalyst plays a vital role to get the highest faradic efficiency in HER process. Interestingly, Volcano plot suggest that MoS_2 is one of the most promising electrocatalyst towards HER. However, the 2D MoS_2 semiconductor has some definite drawbacks over its performance for HER. In this aspect, numerous modification techniques were applied to enhance the catalytic performance of the MoS_2. Among them doping engineering emerges as promising technique to enhance the catalytic efficiency of the MoS_2. Here in, we have tune the MoS_2 catalytic activity by doping with different foreign element like Vanadium (V) and Nitrogen (N) into the layer 2D MoS_2 crystal lattice. The catalytic performance of MoS_2 in acidic and alkaline pH got augmented on incorporation of the V and N over MoS_2. The observed overpotential in acidic and alkaline medium after doping with V (194 & 206 mV) and N (109 & 141 mV) were found to be less than pure MoS_2. This findings provides a novel route to enhance the catalytic activity of MoS_2.

Exploration of Electrical Conductivity of 1D Coordination Polymers (CPs): Recent Trends in Design strategy and Controlling factors

Basudeb Dutta,[a,b]* ChittaranjanSinha,[b] and Mohammad Hedayetullah Mir[a]
[a]Department of Chemistry, Aliah University, New Town, Kolkata 700 156, India.[b]Department of Chemistry, Jadavpur University, Jadavpur, Kolkata 700 156, India. Email: dutta.basu11@gmail.com

The key revolution in material science has been presented on its prospective applications in electrical energy storage, semiconductor devices, new energy resource generation and sensitive switches etc. Numerous organic and inorganic compounds have been synthesized and utilized for progression of electrical and electronic material research. However, in recent consequence, the hybrid materials (i.e. composed of inorganic metal ions and inorganic ligands) mainly coordination polymers (CPs) have been proven to be attractive in laboratory to land applications.Scientists have taken the opportunity of this hybrid nature and designed the requisite materials in order to improve the electrical and optoelectrical.To overcome the energy crisis situation, these CPs may be employed to resolve the issue owing to their outstanding structural diversity and chemical stability. Therefore, judicious selection of structural components of CPs is directly valued the energy-related applications. Here, the rational designing strategy and structural factors that affect the charge transport properties as well as electrical conductivity will be discussed (**Figure 1**).

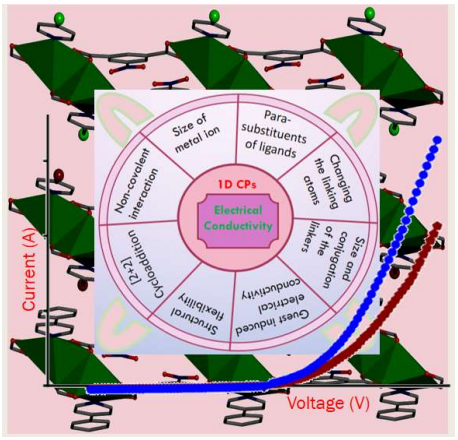

Figure 1. Designing strategy and structural factors that affect the electrical conductivity of 1D CPs.

Selenium Enriched NiSe/NiO Hollow Nano Architecture as a Binder-Free Battery-Type Cathode for High Performance Pouch-Type Hybrid Supercapacitors

Suvani Subhadarshini[1], Dipak K. Goswami[1,2], Narayan Ch. Das[1,3]

[1] School of Nano Science and Technology, Indian Institute of Technology Kharagpur, Kharagpur, India.
[2] Department of Physics, Indian Institute of Technology Kharagpur, Kharagpur, India.
[3]Rubber Technology Centre, Indian Institute of Technology Kharagpur, Kharagpur, India

NiSe-Se@NiO nanostructures were supported on highly conductive nickel foam. They were synthesized using facile chemical bath deposition technique. The densely grown nanostructure, with its large number of electroactive sites, facilitated rapid diffusion and charge transport. The NiSe-Se@NiO@Ni foam electrode, exhibited a superior specific capacitance value of 2704 F g^{-1} at a current density value of 4 mV s^{-1} in a 1 M aqueous KOH electrolyte. Furthermore, a high-energy-density pouch-type hybrid supercapacitor (HSC) device was fabricated using the proposed battery-type NiSe-Se@NiO@Ni foam as the positive electrode, activated carbon on Ni foam as the negative electrode, and a filter paper separator soaked in a 1 M KOH electrolyte solution. The HSC delivered a specific capacitance of 91.68 F g^{-1} at a current density of 6 mA cm^{-2} with an energy density of 0.52mWh/cm^2 at a power density of 22.9mW/cm^2 for an extended operating voltage window of 1.6 V. In addition, the HSC exhibited excellent cycling stability with a capacitance retention of 93.87% after 5000 cycles, highlighting its excellent potential for use in the hands-on applications. The real-life practicality of the HSC was tested by using it to power a red light-emitting diode, a toy motor fan and a PC cooler fan.

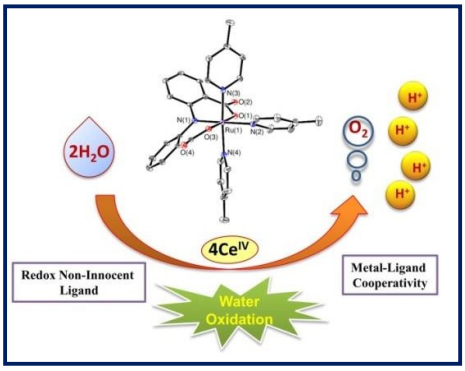
Efficient Water Oxidation Catalyzed by Single-Site Ruthenium(III) Complex with a Redox-Non-Innocent Ligand Framework

Animesh Kundu, and Sukanta Mandal*
Department of Chemistry, Indian Institute of Technology Kharagpur
Kharagpur - 721302, W.B., India
E-mail: sukanta.mandal@chem.iitkgp.ac.in

This work describes catalytic water oxidation activity of a mononuclear ruthenium(III) complex $[Ru(L)(pic)_3]$ (H_3L = 2,2'-iminodibenzoic acid, pic = 4- methylpyridine), using Ce(IV) as an oxidant in pH 1. The detail mechanistic investigations of water oxidation have been carried out by the use of spectroscopy, electrochemistry, kinetic analysis and computational studies. Electrochemical study suggests that water oxidation proceeds via formal high-valent Ru^{VII} species. The capability of accessing such a high valent state is derived from the non-innocent behavior of the anionic-tridentate ligand framework which helps in accumulation of oxidative equivalents in cooperation with metal center. This metal-ligand cooperation is important to facilitate the multi-electron oxidation of water. Mechanistic investigation reveals water oxidation at single-site of Ru where O-O bond formation takes place via



radical-radical coupling pathway between the oxygen atom of ruthenium-oxo species and the oxygen atom of hydroxocerium(IV) ion. This is an important observation from the viewpoint of natural oxygen evolution reaction in Mn_4CaO_5 cluster where the O−O bond formation was proposed to take place through the heterometallic reaction between Mn^{V}=O species and Ca^{II}–OH species.

Keywords: Non-innocent Ligand, Ruthenium Complex, Water Oxidation, Catalysis.

The non-innocent ligand[1-4] H_2LAP(Ph) contained a bulky phenyl substituent at the ortho- position to the aniline moiety. The ligand reacted with 0.5 equivalent of $CuCl_2$•$2H_2O$ in the presence of Et_3N under air and provided the corresponding Cu(II)-bis(imonosemiquinone) complex (**1**). The complex upon oxidation by stoichiometric amount of ferrocenium hexafluorophosphate ($FcPF_6$) yielded the four-coordinate [Cu(II)-(imonosemiquinone)(iminoquinone)]PF_6 complex (**3**), while the oxidation by an equivalent amount of $CuCl_2$•$2H_2O$ produced the five-coordinate Cu(I)-bis(iminoquinone)Cl complex (**2**). Thus, a ligand-based oxidation followed by ligand-to-metal electron-transfer was realized for the latter oxidation process[5]. Removal of the Cl^- ion from complex **2** rendered four-coordinate complex 4. The oxidation state of both Cu(I) and iminoquinone moieties remained unaltered upon the change in the coordination number.

All the complexes were characterized by X-ray crystallography. Complexes 2, 3, and 4 were diamagnetic with a St = 0 ground state as evident by EPR and ^{1}H-NMR measurements. The UV-Vis-NIR spectra of all the complexes were dominated by charge-transfer transitions. Two oxidations and two reductions waves were noticed in the cyclic voltammogram (CV) of complex **1**.[6] Complex 2 and complex 3 underwent one oxidation and three reductions. Unlike complex 3, which experienced ligand-based oxidation, in complex 2 the oxidation was metal-centered [oxidation of Cu(I)-to-Cu(II)] [7]. UV-Vis-NIR spectral changes during the fixed-potential coulometric one-electron oxidation and thereafter, EPR analysis consolidated the metal-based oxidation in complex **2**. Complex **2** was air stable; however, it oxidized KO2 to oxygen molecule and complex 1 was formed in due course as evident by UV-Vis-NIR spectral changes and EPR measurement[8]. TD-DFT calculations have been incorporated to assign the transitions appeared in the UV-Vis-NIR spectra of the complexes.

Transition metal complexes have been studied extensively for their use as anti-cancer drugs because of their diverse spectral, chemical and electrochemical properties. A number of low molecular weight molecules, as well as synthetic and natural products can recognize DNA. The interaction of metal complexes with DNA is now a day's one of the main active area of research at the interface of chemistry and biology. Earlier, platinum based drugs were already in use in clinical application for more than three decades. In this respect, one polymeric copper (II) complex has been synthesized using substituted thiosemicarbazone Schiff base ligand. The synthesized Cu(II) complex was characterized by various physico-chemical studies and single crystal x-ray diffraction. Some biological study of the synthesized complex was also evaluated. DNA binding ability of Cu(II) complex was investigated using UV-Vis and fluorescence spectroscopic, viscosity studies as well as by cyclic voltammetry measurements. The binding constant (K_b) value of the synthesized complex was determined from the absorption spectrum and from the fluorescence spectrum, the Sterm-Volmer constant (K_{sv}) value was determined. From the above K_b and K_{sv} values, the binding of the complex to CT-DNA is revealed to be through partial intercalative mode. The protein (BSA and HSA) binding studies were determined with the help of UV-Vis as well as fluorescence spectral methods. Theoretical molecular docking studies were also carried out to ascertain the interaction pattern of copper (II) complex with duplex DNA. The cytotoxicity profile of the titled copper (II) complex with AGS and A549 cancer cell lines have also been investigated.

Molecular Memory Device Based on a Tetranuclear Organotin Sulfide Cage

Abhishek Mishra
Indian Institute of Technology, Jodhpur
mishra.6@iitj.ac.in

To overcome the problem of data storage and data handling various electronic devices at molecular level are being explored continuously. Molecular organometallic complexes have been considered as the potential candidates for the molecular materials to be used in these devices for their ease of processing, flexibility, being light weight, solubility, stability, and versatility to design.[1] Azoaromatic compounds are known to show switching behaviour[2,3] which encouraged us design a tetranuclear monoorganotin sulfide cage $[(RSn^{IV})4(\mu\text{-}S)_6]\cdot 2CHCl_3\cdot 4H_2O$ (**1**) (R = 2-phenylazophenyl) exploiting the intramolecular N→Sn coordination. It consists of an interesting Sn_4S_6 double decker cage like core in which Sn centers are bridged through μ2-S units. The single crystal x-ray diffraction analysis revealed that it contains four identical Sn possessing distorted trigonal bipyramidal geometry. The complex **1** is further explored as active material for the fabrication of solution-processable resistive memory switching device. I-V characteristics of the device showed an excellent memory behaviour with low write voltage i.e., -1.4 V. The device showed a good ON/OFF ratio of 10^3 with retention time of 10000s.[4] The complex **1** is the first organotin complex to exhibit the memristive behaviour.

Ni(II) Tethered Coordination Compounds As Effective Growth Inhibitors of A Drug Resistant Bacterial Pathogen MRSA

Manasa Kongot and Amit Kumar*
Centre for Nano and Material Sciences, Jain (Deemed-to-be University), Jain Global Campus, Jakkasandra Post, Kanakapura Road, Bangalore 562112, India
manasakongot@gmail.com

Research and development in the field of medicinal chemistry for designing new and sustainable drugs is very crucial due to the expanding population of superbugs and drug resistant pathogens. Medicinal inorganic chemistry or metallotherapy is one of the multifarious approaches to tackle such health challenges. To contribute in this direction, we have developed two potentially bioactive nickel complexeswith a ONS donor Schiff base ligand backbone. The complexes have been characterized with the help of analytical techniques such as IR, EDAX, CHNS, ^{1}H-NMR and ^{13}C-NMR. The solution behavior of compounds in acidic and basic pH conditions were tested and their interaction with a serum carrier protein BSA was evaluated which deliberated that the compounds are quite stable over biological pH conditions and bind protein carriers effectively. Further, the compounds were screened for their inhibitory action against a group of bacterial and fungal species. Interestingly, they exhibited excellent growth inhibitory action against methicillin-resistant *staphylococcus aureus* (MRSA) bacterial species. Further studies to confirm their activity, efficacy and mechanism of action will be done in due course. However, preliminary studies suggest that these complexes hold great potential to act as drug candidates for treating infections by MRSA.

It is desirable yet challenging to synthesize a highly ordered holey carbon nitride material with excess nitrogen atoms for a sustainable solar H_2 evolution. Herein, we report the development of directed highly ordered nitrogen-rich honeycomb-like mesoporous carbon nitride nanosheets by using a novel synthetic approach for this purpose. The unique formation route, surface structure and charge carrier dynamics of the two dimensional holey nanosheets are comprehensively monitored and confirmed by SAXS, HRTEM, AFM, BET, XPS and TRPL analyses. Non-stoichiometric high nitrogen content mesoporous nanosheets with the final stoichiometry of g-C3N4.5 acquiring a high specific surface area (382 m^2 g^{-1}), remarkable pore size (7.2 nm) and sheet thickness ~ 5–6 nm are realized in this first report. This elegant material possesses unique low band-gap energy (2.42 eV). Remarkably, the as-synthesized g-C3N4.5 NSs exhibit a record high photocatalytic H_2 evolution rate of 8180 mmol g^{-1} h^{-1} under the present light irradiation ($420 \leq \lambda \leq 510$ nm) condition. The apparent quantum efficiency is found to be as high as 27.14% at 420 nm and retains its photocatalytic activity for longer consecutive catalytic cycles. Bigger pore size and pore volume, and thin walls leading to shortening of the path length of exciton pairs, efficient charge separation and the prolonged average life time of the charge carriers, and lone electron pairs associated with the excess nitrogen content are found to be the reasons behind the excellent visible light driven water splitting reaction.

Keywords: Mesoporous, photocatalytic, H_2 evolution, exciton.

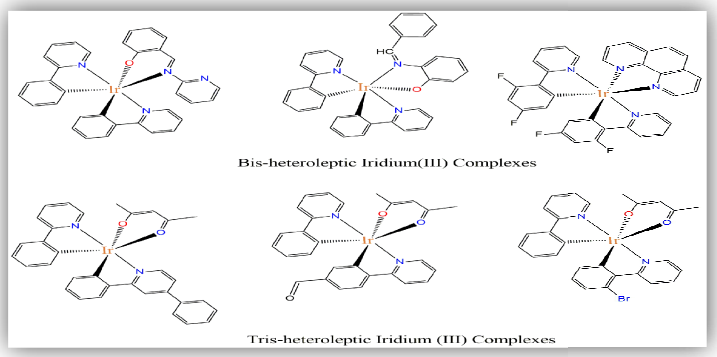
A Short Review on Cyclometalated Iridium (III) Phenyl pyridine Complexes

Kahnu Charan Pradhan, Satyanarayan Pal*
P. G. Department of Chemistry, Utkal University, Bhubaneswar-751004
Kahnucharan1@gmail.com

Cyclometallated Ir(III) complexes as phosphorescence emitters have gained widespread interest as attractive candidates for use in organic light emitting diodes (OLEDs), bioimaging probes[1], oxygen sensors, anticancer agents, photo redox catalysts, pH sensors, and so on because of their remarkable optoelectronic properties. To date, numerous examples of Iridium complexes have been prepared[2] and most of them can be categorized as IrL_3, IrL_2L', IrL_2A, and IrL_2A' where L and L′ are different cyclometallating ligands that chelate to an Ir(III) ion via carbon and hetero atoms, 'A' depicts a symmetric ancillary ligand that binds to Ir(III) via two hetero atoms, and A′ represents a non symmetric ancillary ligand.



Tris-heterolepticIr(III) complexes containing an Ir(III) ion with three different cyclometallating ligands (IrLL′L″) or a combination of two different cyclometallating ligands and one ancillary ligand (IrLL′A or IrLL′A′) represent new classes of highly functionalized Ir(III) complexes, which may open new avenues for the finetuning of their photochemical and electrochemical properties and could fill a function gap between a series of the homoleptic and bis-heteroleptic Ir(III) complexes.

The Phenyl Pyridine and related derivatives have attracted interest as precursors to highly fluorescent metal complexes of possible value as organic light emitting diodes (OLEDs). In all cases, complexation of the metal with the nitrogen donor and metallation at an ortho-position of the phenyl ring gives rise to a five-membered chelate ring.

Now a days the studies on iridium complexes are being designed with heteroleptic iridium complexes composed of phenyl pyridine, substituted phenyl pyridine and ancillary ligands and thus obtained iridium complexes expected to act as phosphors. Each combination of ligands would give rise to HOMO-LUMO separation which would reflect in luminescence behaviour of new complexes. In other words, tuning of emission colour could be achieved through subtle changes in the structure of phenyl pyridine, it's derivatives and ancillary ligands.

A Novel Piperidine Based Schiff Base Sensor for Zn(II) ion with the Formation of Binuclear Zn Complex Having Specific Al(III) Detection Ability in Aqueous Medium and Live Cell Images

Manik Das
Student, Department of Chemistry, Prabhat Kumar College, Contai, Contai, Purba Medinipur, West Bengal, 721404
manikdas12012@gmail.com

A fluorescent Zn(II) sensor **HL** [4-chloro-(((2-(piperidine-1-yl)imino)methyl)phenol] based on piperidine platform have been constructed and properly identified by using various spectroscopic techniques. This organic fluorescence probe **HL** can selectively detect Zn(II) among several analytes This sensing phenomena is convinced by using optical, UV and fluorescence changes of **HL** after adding Zn(II). Dduring conduction of a reaction between **HL** and $ZnCl_2$ sodium azide has been used to form multinuclear complex and as a result of which one Zn complex $[Zn_2(\mathbf{HL})_2(N_3)_4]$ (complex **1**) employing azide as the secondary anionic residue instead of bridging is produced. The single crystal structure of the complex unveils the unique protonation of the piperidine N during the crystallization of the dinuclear motif of the complex. Furthermore due to the presence of remarkable luminescence property the complex **1** have been reutilized to sense Al(III) ion as metalloreceptor in HEPES buffer solution via turn of fluorescence with high fluorescence quenching constant. The DFT study suggests the formation of bimetal complex during sensing of Al(III) with complex **1** as metalloreceptor. The in vitro cell imaging study gives a authentic hints for in vivo biomedical application of **HL** as a Zn(II) sensor. The two step sensing phenomena of **HL** and Zn complex is further established by advanced molecular logic gate formation.

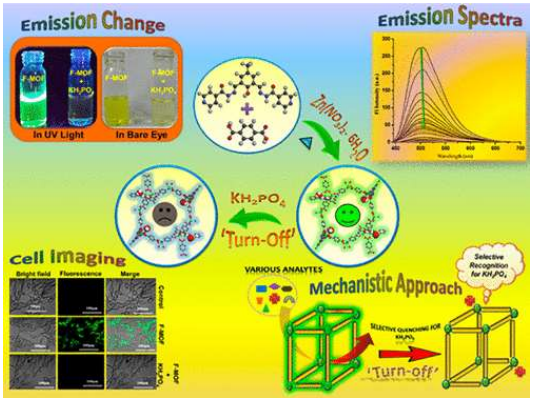
Fluorescent Metal–Organic Framework for Trace Quantity Detection of Inorganic Phosphate as $H_2PO_4^-$

Kaushik Naskar and Prof. Chittaranjan Sinha*
Department of Chemistry, Jadavpur University
naskar.kaushik123@gmail.com



Drinking water quality management and sustainable environment to water bodies are a major concern to public health engineering departments. Inorganic phosphate (Pi), one of the major inorganic pollutants, is addressed for the last two decades regarding trace quantity detection. Over the past few years, a large number of fluorescent metal–organic frameworks (F-MOFs) have been studied to explore the desirable method for selective water analysis. In this article, a Zn(II) 3D F-MOF, {[Zn_2(PCDF-INH)$(BDC)_2$]·(H_2O)}n (**1**) (H_2BDC = 1,4-benzenedicarboxylic acid, and PCDF-INH = *N*,*N*′-diisonicotinoyl-2-hydroxy-5-methyl-isophthalaldehyde dihydrazone), is used for selective recognition of $H_2PO_4^-$ anion by a "turn-off" fluorescent sensing technique. Single-crystal X-ray analysis accounts that the asymmetric unit is constituted of two different Zn(II) centers by PCDF-INH, and the bridging group BDC^{2-} ions are responsible for the generation of the helical polymer and the biporous structures (14.807 × 13.096 $Å^2$ and 24.905 × 24.932 $Å^2$). The compound, **1**, exhibits strong emission at 505 nm in CH_3OH–H_2O solution and is "turn-off" upon the addition of $H_2PO_4^-$. The selectivity and specificity for $H_2PO_4^-$ have been checked in the presence of 15 different anions, including different phosphates (PO_4^{3-}, HPO_4^{2-}, $P_2O_7^{4-}$). The entire sensing activity of **1** is examined by spectrofluorometric method,^{1}H NMR titration, PXRD analysis, and bioimaging study, and the limit of detection is 3.903 μM. However, in vitro biosensing analysis confers that F-MOF (**1**) is sensable toward the $H_2PO_4^-$ ion at a trace level in the human lung fibroblast cells and human liver cancer cell line Hep G2.

Oral Presentation

Green protocol for Synthesis, Characterization and Biological Studies of Transition Metal Complexes of N4-diubstituted Thiosemicarbazones

Vrushali. S. Gavhane*, Anjali .S. Rajbhoj, Suresh. T. Gaikwad
Department of Chemistry, R. B. Attal Arts, Science and Commerce College, Georai, Dist. Beed.
Email: drvrushaligavhane@gmail.com

Complexes of transition metal ions with N-4-disubstituted thiosemicarbazones were synthesized. Salicylidene N-4-substituted thiosemicarbazones were prepared through condensation of salicylaldehyde and N-4-substituted thiosemicarbazides by sonication method. The characterization of newly formed compounds was carried out by ^{1}H-NMR, FTIR spectroscopy, elemental analysis, molar conductance. In addition, the structure of the complex has been determined by X-ray diffraction method.

IR spectrum of ligand and the metal complexes indicate the existence of tridentate nature of ligand which undergo coordination to metal ions with ONS donor atom sets. The ligand and its metal complexes were also tested for biological activities.

Keywords: N-4-substituted thiosemicarbazones by sonication, biological studies.

Insights into Transition Metal Mediated Generations of NO and H_2S

Dr. Subrata Kundu
School of Chemistry, Indian Institute of Science Education and Research Thiruvananthapuram (IISER–Tvm), Thiruvananthapuram – 695551, India
Email: skundu@iisertvm.ac.in

While NO and H_2S are historically known as potent toxins, both the gaseous molecules have recently gained remarkable research interests because of their involvements as gasotransmitters in a diverse array of physiological processes including vasodilation, immune response, and neurotransmission. As a consequence, the generations and utilizations of NO and H_2S in the biological milieu are very tightly regulated through complex chemical pathways. Our research aims tohighlightthe molecular level insights into a number of unique routes leading to the generations of NO and H_2S.

Owing to our interest in disclosing the molecular mechanisms of NO generation from relatively stable NO_x^- anions, we employ a number of isolated nitrate and nitrite complexesbound to copper(II) site. A detailed kinetic study outlines thatphenols are capable of reducing NO_2^-($NO_2^- + 2H^+ + e^- \rightarrow NO + H_2O$) at copper(II) through proton-coupled-electron-transfer (PCET). Intriguingly, the protonation of a proton-responsive secondary coordination sphere leads to a switchover of the underlying mechanism for the phenol mediated nitrite reduction. Notably, the alternative mechanism involving the nitrito-copper (II) hosted by the protonated cryptand discloses an unusual anaerobic route for phenol nitration. While phenol is not capable of reducing nitrate at copper (II) site, hydrazine reacts with copper (II)-nitrate complex to yield NO.

In parallel to the recognition of new NO releasing pathways, this talk will brieflydemonstrate the mechanism of H_2S releasing pathway from CS_2 / COS through the hydrolase activity of a dinuclear zinc (II)-aqua complex. These findings offer a new possible H_2S generating route from CS_2/ COS metabolism mediated by dinuclear hydrolase enzymes.

Keywords: Bioinorganic chemistry • Nitrogen-oxides •PCET •Second-coordination sphere•Hydrogen sulfide

Bioinspired Models of the [FeFe] Hydrogenase Enzyme Using 2-Mercaptobenzimidazole Ligand: Synthesis and electrocatalytic Proton Reduction

Naveen Kumar and Sandeep Kaur-Ghumaan*
University of Delhi, India
Email: skaur@chemistry.du.ac.in,nkumar@chemistry.du.ac.in

Nucleophilic N-heterocyclic carbene ligands (NHCs) are an important class of ligands as they are bulkier and more basic than the ubiquitous phosphines. In order to investigate electrocatalysis for complexes with NHCs, two new iron sulphur complexes,triiron carbonyl cluster $[Fe_3(C_7H_6N_2)(\mu_3\text{-}S)_2(CO)_8]$ **1** and diiron complex $[Fe_2(\mu\text{-}2\text{-mercaptobenzimidazole})_2(CO)_6]$**2** were synthesized. Both the complexes were obtained from the reaction between $Fe_3(CO)_{12}$ and 2-mercaptobenzimidazole. Complex **1** was the major product of the reaction while complex **2** was produced in only minor quantity. The complexes were characterized by various spectroscopic techniques, elemental analysis and mass spectrometry.[1-3] In the triiron carbonyl cluster $[Fe_3(C_7H_6N_2)(\mu_3\text{-}S)_2(CO)_8]$ **1**, the carbene ligand is attached to one of the metal centers, as is also observed from the X-ray structure analysis.Electrochemical studies were also performed on the complexes in the absence and presence of acids. Based on cyclic voltammetric measurements, complex **1** was found to catalyze the reduction of trifluoroacetic acid to produce hydrogen at -1.73 V vs. Fc/Fc^+.[4-8]

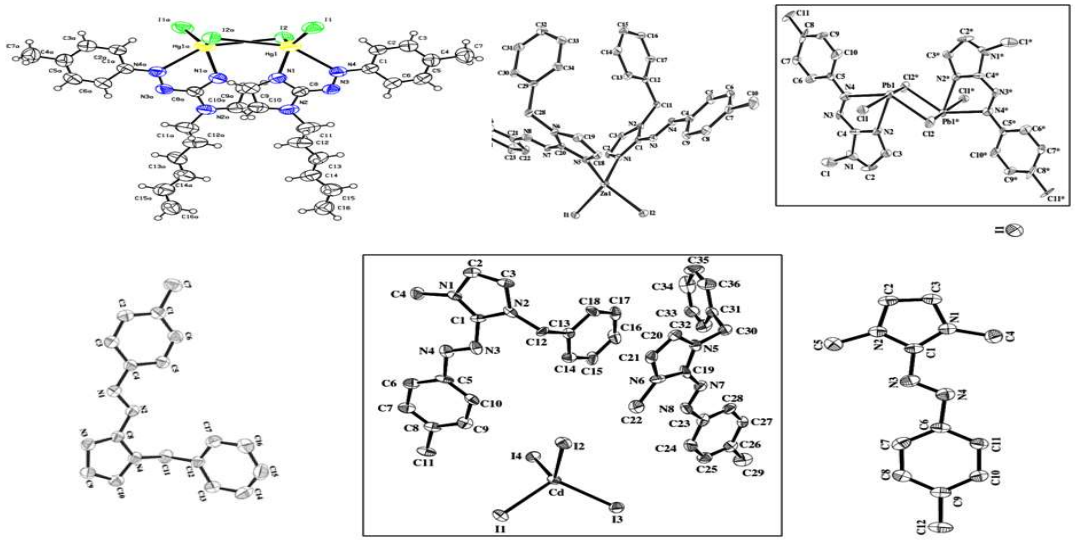
Nontransition Metal Complexes Of Azoheterocycles: Structures And Photochromic Behaviour

Debashis Mallick
Assistant Professor, Mrinalini Datta Mahavidyapith, Birati, Kol-51.
dmchemmdm51@gmail.com

Synthesis and characterisation of some nontransition metal compounds of 1-alkyl-2-(arylazo)imidazoles and 1,3-dialkyl-2-(arylazo)imidazolium ions will be presented. Photochromism of arylazoimidazoles will be discused. The coordination chemistry of Zn(II), Cd(II), Hg(II), Pb(II) and Bi(III) with 1-alkyl-2-(arylazo) imidazoles will be presented along with their photochromic properties in some cases. The complexes are characterized by spectral studies (IR, UV-Vis and ^{1}H NMR) and the structural confirmation has been carried out in representative cases by single crystal X-ray diffraction studies. The electronic properties and photochromic efficiency of the compounds will be explained on the basis of DFT and TD-DFT calculations in some cases.



OP-5

A greener Approach: Oxidation of Fatty Aldehyde In Aqueous Medium

Suman Chowdhury*, Bidyut Saha
Department of Chemistry, The University of Burdwan, Golapbag, Burdwan, WB – 713104
*sumanchem54@gmail.com

Oxidation of long chain aldehydes is truly tough in aqueous medium. So, an attempt has been made to oxidise octanal, a fatty aldehyde, by Cr(VI) in acidic aqueous media with the assistance of surfactants. The detailed kinetics of this successful micellar oxidation reaction has been studied spectrophotometrically under pseudo1st order condition at 25°C (± 0.1°C). In promoting the oxidation reaction three hetero-aromatic bases i.e. 1, 10 – phenanthroline (Phen), 2-picolonic acid (PA) and 2, 2' – bipyridine (Bpy) have been used in combination with the surfactants. Mixture of SDS and Bpy has come out to be the most effective among the others to enhance the oxidation rate maximum. Necessary spectral analysis and thermodynamic facts have also been produced in support of the whole process.

OP-6

Amorphous Zeolites for CO_2 to Fuel and Plastic to Chemical Transformation

Ayan Maity,[1] Sachin Chaudhari,[2] Jeremy J. Titman,[2] and Vivek Polshettiwar[1]*
[1]Department of Chemical Sciences, Tata Institute of Fundamental Research (TIFR), Mumbai, India
[2]School of Chemistry, University Park, University of Nottingham, Nottingham NG7 2RD, UK Email: ayan.maity@tifr.res.in, vivekpol@tifr.res.in

In this work, we report the synthesis and application of a new class of material, called "Amorphous Zeolites (AmZe)"[1], which possesses Brønsted acidic sites like in zeolites and textural properties like ASAs. This was achieved by controlling the hydrolysis and condensation reaction kinetics between silica (tetraethyl orthosilicate) [2,3] and alumina (aluminum acetylacetonate) precursors in a bicontinuous microemulsion template [4-7]. The synergy between strong acidity and accessibility was reflected in the fact that AmZe catalyzed eight different catalytic processes (styrene oxide ring-opening, vesidryl synthesis, Friedel−Crafts alkylation, jasminaldehyde synthesis, m-xylene isomerization and cumene cracking) which all require strong acidic sites and larger pore sizes, with better performance than state-of-the-art zeolites and amorphous aluminosilicates (Figure 1). Notably, AmZe efficiently converted a range of waste plastics to hydrocarbons at significantly lower temperatures. A Cu-Zn-Al/AmZe hybrid showed excellent performance for CO_2 to fuel conversion with 79% selectivity for dimethyl ether. Performance of AmZe for plastic degradation and CO_2 conversion was found to be superior to conventional zeolites. The catalytic activity and selectivity of AmZe was then investigated by conventional and DNP- enhanced solid-state NMR to provide molecular-level understanding of the distinctive Brønsted acidic sites of these materials. Due to their unique combination of strong acidity and accessibility, AmZe will be a potential alternative to hierarchical zeolites.

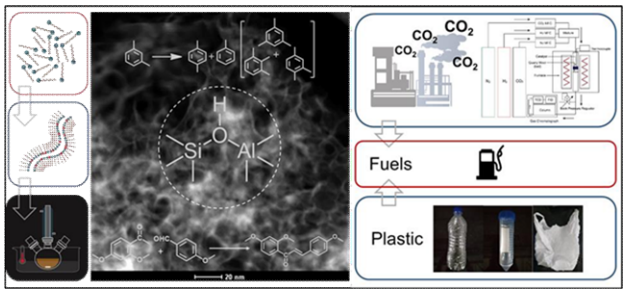


Figure 1. Synthetic Scheme and application of Amorphous Zeolites (AmZe) in CO2 to fuel and plastic to chemical conversion.

Easily Extraction of Arsenical Ferrihydrite from Water at Varied pH By Zinc Acetate and Consequent of Mineralization

Sanjit Das
School of Materials Science, Indian Association for the Cultivation of Science, Jadavpur, Kolkata 700032, India.
mssd5@iacs.res.in,

Natural iron oxyhydroxide nanoclusters in water, broadly named as ferrihydrite (Fh), has a serious role in water remediation as Fh is known to form inner sphere complexes with many inorganic contaminants, thereby acting as an efficient adsorbent of Arsenic and heavy metals. However, difficulty lies in extracting such clusters from water at low concentrations and varied ranges of pH other than the pH of their respective point-of-zero-charge (PZC) because repulsive forces between their charged surfaces keep the clusters as stable colloidal suspension. Therefore, the only possible methods of removal seem to be microfiltration or sweep flocculation creating large amount of unstable toxic sludge. Here we show that, it is indeed possible to extract these 'soluble' nanoclusters out of water by charge neutralization, if effective coagulants of opposite surface charges are applied. This is achieved here by simply adding a limited amount of commercial zinc acetate salt. Ferrihydrite is a crucial sequester of arsenic, but leaching of arsenic (As^{3+}, As^{5+}) is one of the fatal drawbacks of Fh.The present study tries to explore an alternative pathway for formation of tooeleite-like mineral staring from arsenical ferrihydrite, which is the only known mineral containing Fe(III) and As(III) and can ensure safe disposal of As(III).

Pore-Functionalized and Ultralight Charged MOF with Color Tunable Emission for Anticounterfeiting Applications *via* Specific Tb^{3+} Sensitization

Nilanjan Seal, Subhadip Neogi*
Academy of Scientific and Innovative Research (AcSIR), Ghaziabad-201002, India
Inorganic Materials and Catalysis Division, CSIR-Central Salt & Marine Chemicals Research Institute, G.B. Marg, Bhavnagar 364002, Gujarat, India
Email: nilanjan.seal5@gmail.com,

Counterfeiting is a long standingglobal problem that poses threats to the safeguard of individuals' data and creates huge negative impact on the development of global economy.[1] Among various anticounterfeiting protocols, fluorescent materials such as carbon dots, perovskite nanocrystals, and cadmium chalcogenide quantum dots are widely utilized owing to their high photoluminescence (PL) intensity/efficacy and tunableexcitation/emission wavelength. But,due to several disadvantages of these materials; [2] modern anticounterfeiting techniques demand fabrication of advanced composite material with tunable photoluminescence quantum yield, where lanthanide based luminescent materials are specifically important owing to their unparalleled spectroscopic attributes.[3] Such most anticipated composite system has been realized in an ultralight, anionic metal-organic framework (MOF)**CSMCRI-4**, constructed from Li^{+} ion and 4,4',4''-tricarboxytriphenylamine (H_3TCA) ligand.[4] Benefitting frompore-occluded dimethylammonium ions, the framework provides an opportunity to selectively exchange these cations with Tb^{3+} ions, which are stabilized inside the MOF cavity through binding with the free oxygen atoms at the inner surface of pore. Interestingly, Tb^{3+} is sensitized through antenna effect and modulates the pristine bright blue emission of the MOF to green. Such dichromatic emission modulation has been efficiently harnessed in developing anticounterfeiting label for potential anti-forgery applications over multiple platforms.

Facile Synthesis and Characterization of Heteroatom Doped Graphene Quantum Dots

Reena Suryawanshi and Kallol K. Ghosh*
*School of Studies in Chemistry, Pt. Ravishankar Shukla University, Raipur-492010
E-mail: reenasuryawanshi1994@gmail.com

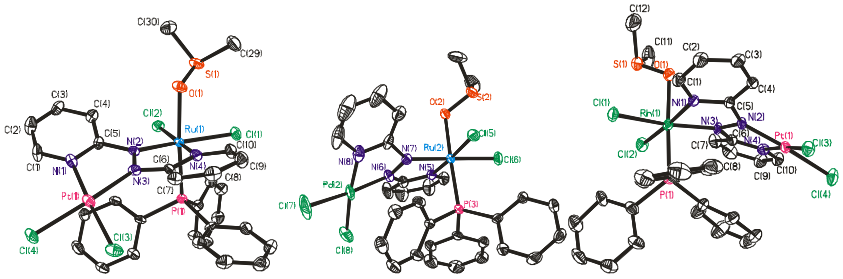
Doping of graphene quantum dots (GQDs) with heteroatom effectively alters its electronic and optical properties. Herein, we report a facile bottom up method for synthesis of boron doped GQDs (BGQDs) and nitrogen, sulphur co doped GQDs (NS-GQDs). The characterization was done by UV-vis, fluorescence and FTIR spectroscopic techniques. The stable fluorescence of heteroatom doped GQDs indicates that they can be used as biosensor for clinical and medical studies, as imaging and sensing. FTIR spectra confirm the presence of different functional groups and effective doping onto the surface of GQDs. The effect of pH has also been studied which indicates that particle size distribution increases with increasing of pH.

OP-10

Hetero Bimetallic Anion Radical Complexes of Azobispyridine

Dr. Suvendu Maity
Department of Chemistry, Jadavpur University
suvendumaity99@gmail.com

Coordination induced spin state conversion from the $^3O_2$ to $^1O_2$ and the electron transfer from the metal ion to $^1O_2$ are significant phenomena in the bioactivity of the O_2 molecule. Upon coordination, O_2 molecule is transformed to superoxide in hemoglobin and myoglobin, to peroxide in hemocyanine and p-450, to hydroperoxide in hemerythrin. Thus, the coordination induced electron transfer from the metal ion to the coordinated molecule is a subject of investigation in chemistry. $^3O_2$ molecule is a weaker ligand due to its stabilized σ orbitals and occupied π* orbitals and exhibits poor synergistic effect. Formation and stabilization of azo anion and diimine anion radicals in the complexes of transition metal ions were documented in literature. In this report, the coordination induced electron transfer from a t_{2g} level of ruthenium(II) and rhodium (II) ion to -N=N- fragment, when both the N atoms coordinate the metal ions. Bimetallic complex of Ru-Pd, Ru-Pt and Rh-Pt are most important in the synthetic and chemical point of view. These hetero bimetallic complexes show the lower region band due to metal to metal (intravalent charge transfer) transition band.



Ru-Pt **Ru-Pd** **Rh-Pt**

OP-11

A Smarter Approach towards Environmental Remediation: Strategic Construction of Functionalized MOFs for CO_2Scavenging and Ultra-Sensitive Detection of Multifarious Aqueous Pollutants

Ranadip Goswami,[†‡]**& Subhadip Neogi***[,†‡]
†Inorganic Materials & Catalysis Division, CSIR-CSMCRI Bhavnagar, Gujarat-364002,India ‡Academy of Scientific and Innovative Research (AcSIR), Ghaziabad-201002,India
iamroni1993@gmail.com

Metal–organic frameworks (MOFs) show distinctive superiority for carbon dioxide (CO_2) capture and luminescent sensing of toxic pollutants over other materials, where combination of both of these properties together with improvement of hydrolytic stability and pore functionality is critical to environmental remediation applications.[1,2] In view of these facts we strategically synthesized the dual functionalized MOF,**CSMCRI-2** thatfeatures unique analyte-responsive turn "on–off–on" fluorescent switching towards toxic sulfadiazine (SDZ) and nitrofurazone (NZF) antibiotics[3] with nano-molar limit of detection (LOD). This MOF further shows exceptional "turn-on" detection of adenosine monophosphate (AMP) (~14 fold) in concurrent presence of interfering biophosphates, with 10 nM LOD. Importance of pillar functionalization in such unique fluorescence alteration is explicitly validated by density functional theory (DFT) calculations that provide proof-of-concept to the sensing mechanism.Alternatively,the cationic and chemically robust Ni(II)–organic framework (**CSMCRI-3**), with nitrogen rich pore surface benefits moisture tolerant CO_2 capture with exceptional selectivity over other gases (CO_2/N_2 :292.5) alongside remarkable muticyclic usability. Owing to the hydrolytic stability, this mixed-linker MOF exhibits ultra-low detection of nitro-explosive (Picric acid) and toxic oxo-anions (chromate, dichromate and manganate) in water with sharp colorimetric changes in highly selective and regenerative manner.[4]

Enhanced Stability of Curcumin in Presence of Cu^{2+} ion : A HPLC Study and Its Biological Attributes on Bacterial Strains

[a]Tanmoy Saha, [a]Mouli Saha , [a]Promita Nandy , [b]Prince Kumar, [b]Kasturi Mukhopadhyay* and [a]Saurabh Das*

[a]Department of Chemistry (Inorganic Section), Jadavpur University, Kolkata – 700 032, India.

[b]School of Environmental Sciences, Jawaharlal Nehru University, New Delhi – 110 067, India.

tsaha.chemistry@gmail.com

In an attempt to overcome limitations of Curcumin in biology and medicine, a monomeric complex of $Cu^{II}[(Cur)(OCOCH_3)(H_2O)]$ was prepared. Using HPLC, it could be realized, under physiological conditions Curcumin is not a "single-unit" either in aqueous solution or in cellular medium. Hence, to understand things better it became essential to identify fragments actually responsible for the reported efficacy of Curcumin (or to have it in solution as a "single-unit". Hence, to prevent Curcumin from degrading (verified by HPLC) before it interacts with a biological target and to improve bio-availability a complex of it with Cu(II) was attempted. Metal bound Curcumin remains a "single-unit". Besides, presence of a metal ion might assist in cellular uptake or address issues related to solubility. Antibacterial efficacy of Curcumin and its Cu(II) complex were explored against clinically significant bacterial strains *Staphylococcus aureus* and *Escherichia coli*. Cu(II) complex was more effective than Curcumin that may be considered an attribute of complex formation The complex being membrane targeting was able to permeabilize the cytoplasmic membrane of *Staphylococcus aureus* that makes it a better bactericidal agent than curcumin. Toxicity studies revealed Cu(Cur) had very little side effects on mammalian cells making it relatively safe as an antimicrobial agent for the host. The study is also an effort to realize the increased stability and efficacy of a non-toxic Cu(Cur) on *Staphylococcus aureus* over that of Curcumin.

Preparation of Metal Complexes with Picramic Acid

Dr. Chandana Kumari
Lecturer at S.J.M College Bhagalpur, P.G Department of Chemistry, T.M Bhagalpur University
Bhagalpur 812007
chandana.kumari501@gmail.com

There are various of metal complexes form various ligands which have been known since long time and synthesis and their and their application of new ligand are always being tried in order to prepare varieties of complexes. In this way, picramic acid, ($C_6H_5N_3O_5$) which is 2-Amino-4-6- dinitrophenol has been prepared in this laboratory and its complexes with copper (II), mercury(II) and $UO2^{2+}$ has been prepared. The characterization of these complexes has been done in terms of elemental analysis, IR and UV-Spectra and melting points. Dehydrated $CuCl_2$ was treated with alcoholic solution of picramic acid and the solution of picramic acid and the solution was refluxed to give deep blue crystal (mpt.=135°c). Alcoholic solution of picramic acid was treated with dry uranyl nitrate then deep blue crystal were obtained (mpt.=162°c). Deep brown crystals were obtained when mercury chloride was refluxed with alcoholic solution of picramic acid (mpt.=158°c).

Synthesis, Characterization And Antimicrobial Studies Of Co (II) Complexes Of Bidentate Schiff Base Ligand 2-(Benzylideneamino) Pyrimidine-4, 6-Diol

D.T. Sakhare
U.G, P.G. & Research Centre, Department of Chemistry, Shivaji, Art's, Comm. & Science College Kannad, Dist. Aurangabad. 431103, (M.S.) India.
sakharedhondiram@yahoo.com

The transition metal complexes of Co (II) were prepared from bidentate Schiff base. The Schiff base ligand synthesized from the condensation of Benzaldehyde and 2- amino-4, 6- dihydroxypyrimidine (L) in alcohol medium. The metal complex was characterized on the basis of their micro analytical data, molar conductance, magnetic susceptibility, IR, UV-Vis, ^{1}H NMR, X-ray diffraction, thermogravimetric analysis. The ligand and their metal complexes were screened for fungicidal activity against various fungi like Aspergillusniger, Penicilliumchrysogenum, Fusariummoneliforme and Aspergllusflavus.and antibacterial activity against various bacteria likes Escherichia coli, Salmonellatyphi, Staphylococcus aurious, B.subtilis. The result indicated that the complexes exhibited good antifungal and antibacterial activities.

Keywords: Schiff bases, Transition metal complexes, Thermal analysis, Powder X-ray diffraction, Antimicrobial activity.

PdSn Hollow Alloy Nanostructure Prepared by Low Cost Hydrothermal Approach and Auto Galvanic Replacement Process for Robust Electrocatalysis Towards Hydrogen Evolution Reaction

Ankur Kumar[1], Sasanka Deka[1]*
Department of Chemistry, University of Delhi, North Campus, Delhi-110007
ankur93dhiman@gmail.com

Nanostructured hollow PdSn alloy system introduced as highly efficient electrocatalyst for hydrogen generation using electrocatalytic water splitting reaction. Hollow $Pd_{1-x}Sn_x$ (x=0.0–1.0) alloy with different composition having large electrochemically active surface area for producing hydrogen in 1M H_2SO_4 electrolyte solution. Due to different redox potentials of Pd and Sn and in-situ galvanic replacement process hollow PdSn alloy nanoparticles generated. The as-synthesized alloy nanoparticles have fcc crystal structure exposed with {111} facets. Among various compositions $Pd_{0.6}Sn_{0.4}$ exhibits excellent catalytic activity towards hydrogen evolution reaction to reach an overpotential of 68 mV to attain current density of 10 mA cm^{-2}. A lower Tafel slope (58 mV/dec) value with high exchange current density (114.63 mA cm^{-2}) for rapid electron migration observed during electrocatalytic study of $Pd_{0.6}Sn_{0.4}$ sample. The catalyst also showed long term cycling stability without any deviation for 6000 cycles and durability for maximum 48 h at high constant current density (100 mA cm^{-2}) which depicts its robust electrocatalysis.

Keywords: PdSn alloy; hollow nanoparticles; galvanic replacement; hydrogen evolution reaction; water splitting.

Kinetic study of the photo degradation of Azo dye in photo-ferrioxalate system

Pradyut Sarma
Department of Chemistry, Arya Vidyapeeth College, Guwahati, Assam, India
gu_123456@yahoo.com

An attempt has been made to study the kinetic of the photochemical degradation of commercial azo dye, acid orange 7. Waste water coming from different industrial fields contains azo dye as industrial effluent and they are resistant to common waste water treatments. Photo chemical degradation of those azo dyes, therefore, may an effort to reduce the damaging impact of them In this work, photocatalysis of $Fe(ox)_3$ in the presence of H_2O_2 and sun light has been studied[1]. The kinetic study of the photo degradation of the dye is dependent on various parameters like pH of the solution, concentration of H_2O_2, molar ratio of ox/Fe(III) etc. The reaction kinetic is showed to pseudo first order and suitable at moderate acid pH value 3 - 4. The molar ratio of oxalate ion/ Fe(III) up to 3 is most favourable for the degradation reaction.

Anticancer, DNA/HSA Binding Ability of Three Cu (II) Complexes Having Three Piperidine Based Schiff Base Ligand: A Combine Package of Practical and Theoretical Study

Tithi Maity
Assistant Professor, Department of Chemistry Prabhat Kumar College, Contai, West Bengal, India, 72140
titlipkc2008@gmail.com

Here in we have reported the developed three Cu(II) complexes, Cu(L1)N_3(1), [Cu(L2)N_3]n(2), Cu_2(L3)2(N_3)2(3) incorporating three different piperidine based Schiff base ligand HL1, HL2, HL3 respectively and identified properly by using different spectroscopic method. The single crystal structure reveled that complex 1 is a mono nuclear squre plannar unit with azide as a secondary anionic residue, complex 2 has 1D polymeric structure where two Cu center is connected via azide bridge and complex 3 possess a binuclear distorted octahedral structure having two azide bridge. After rigorous characterization the three complexes are exploited to check their biomedical application and for this purpose initially their binding potentiality against DNA and HSA protein has been examined by adopting several spectroscopic techniques. Experimental results unveil the potentiality of three complexes to associate with DNA/HSA and this is properly justified by molecular docking study. In nest step the anticancer effect of these three complexes is inspected by using MTT assay technique and results show that three complexes has effective anticancer property with low toxicity to the normal cell.

Effect of Photochemical [2+2] Cycloaddition Reaction of Coordination Polymers (CPs) For the Exploration of Potential Applications

Basudeb Dutta[†], Angeera Chandra[Ψ] and Chittaranjan Sinha[Ψ]
[Ψ]Department of Chemistry, Jadavpur University, Kolkata 32
[†]Department of Chemistry, Aliah University, New Town, Kolkata 156

The exploration on metal and organic ligand composed coordination polymers (CPs) has been incipient at an astonishing pace from its existence. The promising applications and essential diversity in structure of these materials are the driving force behind the extensive research of such kind. Inorganic metal ions and organic ligands (carboxylate, sulphate etc.) or neutral donor molecules (N, S donor's based pyridyl and thiophen etc.) are contented to formulate these polymeric coordination compounds. This is the leading accessories to the advancement of solid-state coordination chemistry which is termed as 'crystal engineering' presented by Schmidt. Although, this terminology has been used in regard to the solid-state photochemical [2+2] cycloaddition reaction, for first time. Subsequently, this [2+2] cycloaddition reactions have been unveiled with in the CP systems and resulting structural transformation promotes different potential applications: gas sorption, magnetism , sensing , dielectric property ,isolation of new organic ligand ,electrical conductivity, photo salient effect ,flexibility and elasticity of materials. Therefore, herewe are searching out the contribution of [2+2] cycloaddition reaction of CPs for the impact of different applications.

Two New Copper Based MOFs and Their Magnetic Properties

Nidhi Goel
Department of Chemistry, Institute of Science, Banaras Hindu University, Varanasi, India,
nidhigoel.chem@bhu.ac.in

The area of research in the progress of porous metal-organic frameworks has attracted much attention due to their potential applications in field of catalysis, luminescence, drug delivery, separation, gas storage, and many more.[1] Although, the preparation of metal-organic frameworks depends upon the nature of organic linkers as well as the metal ions.[2] Over the past decades, the metal-organic frameworks having Cu (II) metal ions and flexible ligands have been interesting due to the possibility of antiferromagnetic coupling of metal centers.[3] Therefore, two new copper metal organic frameworks having 1,2-bis(4-pyridyl)ethane, Adipic and Pimelic acids have been synthesized and structurally characterized. MOFs 1 and 2 exhibit three-dimensional and two-dimensional networks, respectively. The magnetic properties of 1–2 have also been investigated, and displayed the antiferromagnetic coupling between the Cu(II) metal centres.[4]

Recent Trends in Chemical Sciences

Dr. Gunjan Kumari
AnandVihar, Ward No-02, Madhepura (Bihar)
gunjanksanjay@gmail.com

A number of broader social trends are shaping the research in chemical science such as ageing population leading to growth in demand of medicine to prevent, control and treat age-related conditions. Such research and development will be key to the future of chemistry. The chemical sciences have the potential to solve many of the world's greatest challenges in health, energy and climate-changes.

At present diabetes at global level, especially in India, is in alarming situation and posechallenges for chemists to prevent and cure this health problem.

In this regard Schiff base of metformin and their metal complexes will be very useful to help prevent type-2 diabetes. This paper presents finding on Schiff base of the metformin benzothiozol derivatives and their metal complexes which are very effective in anti-diabetic activity and shows decrease in glucose level to significant extent at different interval of time. Metformin complexes with cobalt has maximum potency to reduce blood glucose in hyper-condition. First of all, Schiff base legand of MTF with benzothiozol was prepared by mixing aquous solution of MTF and benzothiozol, then complex of Co(II) was prepared. This complex was analyzed with the help of IR, NMR, etc. Biological activity of Schiff base and their complexes were tested as anti-diabetes which proved to be effective against diabetes.

Ancillary Ligands Effect on Emission Behavior of Iridium(III) Complexes

Satyanarayan Pal*, Kahnu Charan Pradhan
P. G. Department of Chemistry, Utkal University, Bhubaneswar-751004
snpal75@gmail.com

Iridium(III) complexes with phenyl pyridine based ligands are usually be emissive in solution and solid states. The complexes were designed with two phenyl pyridines and an ancillary ligand. The ligands coordination around iridium(III) centerprovide an octahedral geometry as well as suitable HOMO-LUMO separation for luminescence behavior. The phenyl pyridine based ligands make the decisive energy gap, whereas the third ligands further tune the emissioncolour. A series of Iridium (III) complexes were synthesized with phenyl pyridine (ppy), difluoro substituted phenyl pyridine (F2ppy), pyridine aldoxime (pyrald), and Shciff base (sb) ligands of formula $[Ir(ppy)_2(pyald)]$, $[Ir(ppy)_2(sb)]$, $[Ir(F2ppy)_2(pyald)]$, and $[Ir(F2ppy)_2(sb)]$. The luminescence studies of these complexes revealed that $[Ir(ppy)_2(pyald)]$ and $[Ir(ppy)_2(sb)]$ were non-emissive, whereas $[Ir(F2ppy)_2(pyald)]$ and $[Ir(F2ppy)_2(sb)]$ were found emissive. Theobservation was reasoned that fluoro substituted ligands provides the suitable energy gap to the observed emissive light. The complexes were weakly emissive which could be due the effect of coordinating third ligand which might have enhanced the non radiative decay processes. The higher HOMO-LUMO energy separation revealed through theoretical calculations could be another reason in support of the non-emissive behavior of the Schiff base complexes.All the new complexes were thoroughly characterized by different analytical and spectroscopic methods. The molecular structures were confirmed using single crystal X-ray structure determination method.

Phosphate-Diester Molecular Templates for the Encapsulation of Water Dimer

Vivek Gupta[a], Vadapalli Chandrasekhar[b]* and Anukul Jana[b]*
[a]Department of Chemical Sciences, Indian Institute of Science Education and Research Berhampur, Transit Campus, Govt. ITI Building, Engineering School Road, Ganjam, Berhampur-760010, Odisha, India
[b]Tata Institute of Fundamental Research Centre for Interdisciplinary Sciences Hyderabad-500107; vc@tifrh.res.in, ajana@tifrh.res.in

The study of water clusters in a confined state has received considerable attention.[1] The simplest among such assemblies of water molecules is the water dimer. Distinct water dimers were characterized via a matrix isolation method[2] and as an endohedral motif in C70,[3] as well as in the interiors of cage-like structures of some organic compounds.[4] Stabilizing this unit at ambient conditions in an appropriate host-template, however, has remained a challenge. Herein, we report 2,6-(diphenylmethyl)-4-iso-propyl-phenyl substituted phosphate diesters (both in their neutral and anionic forms) as molecular templates for hosting the water dimer.[5]

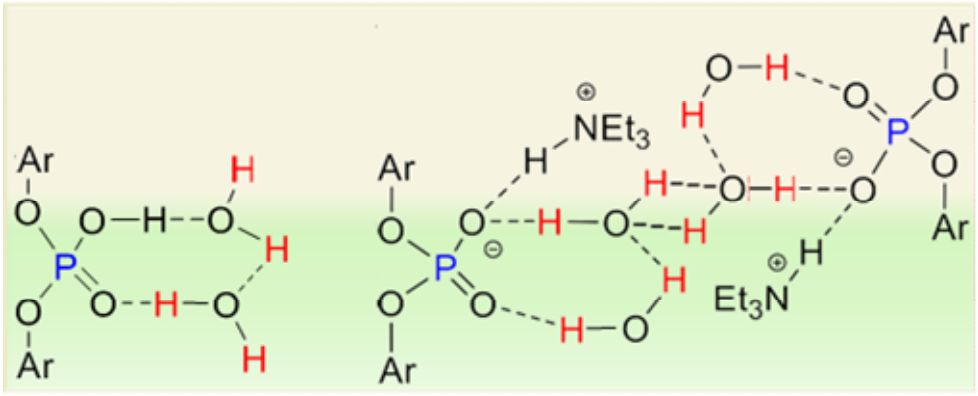

Figure 1. Phosphate diesters as molecular templates for hosting the water dimer

aadakchem@gmail.com

A new fluorophore Rhodamine B with 2-Hydroxy-5-methoxy-3-nitrobenzaldehyde Schiff base dyad (**HSR)** isdesigned and its optical behavior toward various metal ions has been examined in MeCN–H_2O (1:1, v/v; HEPES buffer, pH, 7.4) solution by both UV-vis absorption and fluorescent techniques. The **HSR** achieves tuning the high sensitivity, and selectivity to Al^{3+} ions in the spectroscopic studies via chelation-enhanced fluorescence (CHEF)), while other metal ions including Na^+, K^+, Mg^{2+}, Ca^{2+}, Ba^{2+}, Cr^{3+}, Mn^{2+}, $Fe^{2+/+3}$, Co^{2+}, Ni^{2+}, Cu^{2+}, Zn^{2+},Cd^{2+}, Pb^{2+},Tb^{3+}, Gd^{3+}, Sm^{3+}, Ag^+, Hg^{2+}, Sn^{4+}, Pd^{+2}, Pt^{2+}, Rh^{3+}, Ru^{3+} ions induced commonly no spectral change. The evidence of possible sensing mechanism has been done by FT-IR, Mass spectra, ^1H NMR titration, Benesi-Hildebrand plot, Job's plot, and DFT technique. Upon interaction withHF_2^- ions, the fluorescent signal intensity of resultant $[SR–Al]^{2+}$ complex quenches (weakly quenching by F^- and PO_4^{3}). This constitutes a reversible sensor for Al^{3+} ions HF_2^- ions, respectively.The limit of detection for Al^{+3} and HF_2^- are 19.4 nM and 65.6 nM respectively. The **HSR** has certain practical applicability such as the construction of the logic gate (**INHIBIT)** and to detect Al^{3+} ions in intracellular Human breast.

Development of bis(trimethylsilylemethylene)Tellurium Diiodide

Priyanka Singh and Dr.Pushpendra Singh
Department of Chemistry Dr. Shakuntala Misra National Rehabilitation University Lucknow
Mohaan Road Lucknow- 226017 UP India
psbbkup@gmail.com

Available routes to organotellurium(IV) derivatives are oxidative addition reactions, electrophilic substitution reactions, and insertion reactions of elemental tellurium across the carbon–halogen bonds [1]. First time we are able to isolate, bis(trimethylsilanemethyl)tellurium(IV) diiodide, $(Me_3SiCH_2)_2TeI_2$ in good yield at high temperature. Activation of the C-I bond by trimethylsilane group appears to be insufficient as the reaction takes place only at high temperatures.

Keywords: Silyl, Iodided, Insertion, Tellurium, Room Temperature

Biocompatible Porous Ceramics Based on Black Colored Calcium Phosphate Powders

Dr. Tatiana V. Safronova, Mr. Andrey S. Kiselev, Ms. GilyanaK. Kasakova, Ms. Snezhana A. Tikhonova, Dr. Tatiana B. Shatalova
Lomonosov Moscow State University, 119991, Russia, Moscow, Leninskie Gory, 1,
t3470641@yandex.ru

Porous resorbable ceramic materials based on calcium phosphates is necessary to treat the bone defects of critical size using advancedmethods of regenerative medicine.

Porous materials with a given geometry of the pore space were made using three-dimensional stereolithographic printing from a suspension of black colored inorganic (calcium phosphate) fine powder in a mixture of monomers, polymerization of which occurs under the influence of ultraviolet radiation. Powders were preparing from calcium salts of carboxylic acids and ammonium hydrophosphate followed by thermal treatment at 500-900^{o}C.

Fig. 1. Macroporous material before firing, which is a composite of "polymer/black colored calcium phosphate powder " (left) and macroporous calcium phosphate ceramic material after firing (right). The length of the sample before firing was 11.6 mm, and after firing – 6.1 mm.

The use of the black-colored calcium phosphate powders gives an opportunity to enhance the lateral resolution of stereo-lithographic printing.

Removal Of Cadmium From Water By Adsorption On Newly Synthesised Adsorbent Chitosan Impregnated With Carbon Nanoparticle

Chandra Prakash[1], Ganesh Kumar Choudhary[2], Vimla Choudhary[1]
[1]Department of chemistry, JNV University, Jodhpur
[2]Govt. P.G. College, Barmer
cp26490@gmail.com, dr.vimlachoudhary@gmail.com

Carbon nanoparticle Impregnated chitosan beads synthesized by using honey (green method) was investigated for uptake capacity of cadmium in batch studies. The concentrations of cadmium were measured using ICP-OES with constant adsorbent dosage 0.1g/100ml. As the initial concentration of cadmium is increasing the adsorption capacity is increasing at constant adsorbent dosage. Highest adsorbent capacity was found to be 76.77(24.62 mg/0.1g) when the initial concentration is 200ppm. Highest adsorption percentage removal of cadmium was observed 87.28% when the initial concentration is 200ppm. As the concentration increases there is no significant increase of adsorption percentage was observed, this may be saturation of 0.1g of adsorbent. The effects of various factors such as adsorbent dose, pH, contact time, cadmium concentration are under investigating.

Keyword: Chitosan, adsorption, carbon nanoparticle

Biological,Photophysical and Catalytic Activitiesof Group 6 and Group 8 Metal Carbonyl Complexes Containing Coumarinyl azo/imine Ligand

Dr. Papia Datta
Department of Applied Science (Chemistry), RCC Institute of Information Technology
Beliaghata, Kolkata
papiaju@yahoo.in

Group 6 and Group 8 metal carbonyl complexes containing coumarinylazo and imine ligand are very rich category of complexes having numerous activities. Group 6 metal carbonyl complexes of N-[(2-Pyridyl)methyliden]-6-coumarin (L) show anti-oxidant property and solvatochromism. These complexes possess very good antioxidant activity both in cell free system and in-vitro. $[W(CO)_4(L)]$ exhibits the strongest free radical scavenging activity compared to $[Cr(CO)_4(L)]$and $[Mo(CO)_4(L)]$. On the other hand Os(II) hydridocarbonyl complexes of coumarinylazoimidazoles are photostable and show photovoltaic power conversion efficiency. In addition, theses complexes were used as catalysts for the oxidation of primary/secondary alcohols to aldehydes/ketones using oxidizing agents like N-methylmorpholine N-oxide, t-BuOOH and H_2O_2.

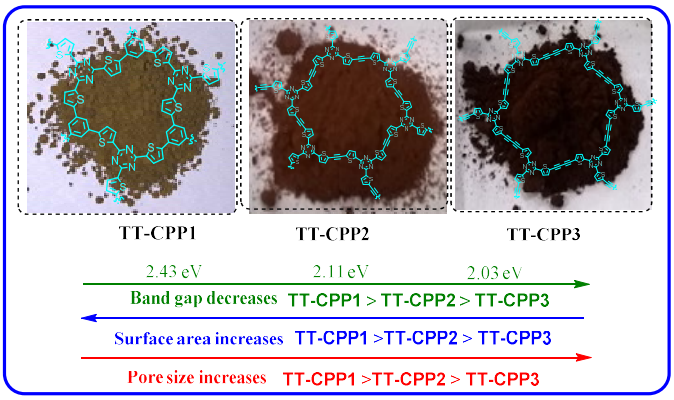
Band Gap Engineering And Gas Adsorption in 2,4,6 tri(thiophen-2-yl)-1,3,5-triazine Conjugated Porous Polymers Of Tunable Porosities

Neha Rani Kumar and Sanjio S. Zade *
Department of Chemical Sciences, Indian Institute of Science Education and Research (IISER) Kolkata, Mohanpur 741246, India.
nehakumar0926@gmail.com

A series of four thiophene and nitrogen containing conjugated porous polymers with the same monomer but with optical band gaps ranging from 2.03 to 2.43 eV is synthesized using the conventional alkyne cyclotrimerisation reaction for **TT-CPP1**, Sonogashira coupling reaction for **TT-CPP2**, Glaser coupling reaction for **TT-CPP3** and Stille coupling reaction for **TT-CPP4**. By varying the spacer between the monomer, the porosity as well as the band gap have been engineered efficiently. The presence of triazine and thiophene moieties within the copolymer network increases the electron donating basic N and S sites in the porous frameworks. Thus, these porous polymers displayed efficient adsorption of Lewis acidic CO_2 molecules. The maximum CO_2 uptake of 11.4wt% (2.6 mmol g^{-1}) at 273 K under 100 kPa pressure has been observed for **TT-CPP1**. The structure–property relationship established in these thienyl triazine based narrow band-gap conjugated porous polymers will be important for rational material design towards applications in organic electronics, gas adsorption and water splitting.



Design and Characterization of Quinoline-3-Carboxamides as Selective Inhibitors of ATM Kinase for Cancer Therapeutics

Kinases of the DNA Damage and Repair (DDR) pathway play a pivotal role in maintaining the integrity of our genetic material. As most of the cancer chemotherapeutics and radiotherapy destroy cancer cells by causing DNA damage, the hyperactivity of these kinases causes resistance to such treatments. Therefore, it is essential to target them for effective treatment of cancer. We aimed to target the key mediator of the DDR pathway, the ATM kinase, which is responsible for DNA double-strand break (DSB) repair. On inhibiting its kinase activity, DSB repair process is hindered, leading to the accumulation of DNA DSBs, and finally, cell death.We designed quinoline-based inhibitors for ATM based on the evidence that the quinoline nitrogen binds to the hinge region of PI3K-γ (close homolog of ATM). Cytotoxicity studies for the synthesized compounds were performed incancer cell lines and HEK293T. Three of the synthesized compounds showed significant cytotoxicity against the cancer cell lines. Western Blotting analysis indicated the inhibition of ATM kinase. The docking score for the compounds in ATM was in the range of -9 to -10.5. The compounds were also docked with other similar kinases, but the dock scores were not significant compared to that of ATM.

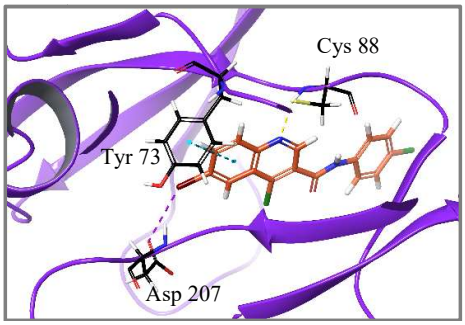

Figure 1. Compound 6f docked with ATM kinase

Phosphine Free Manganese Pincer Complexes: Catalyst Development and Utilization in C-C and C-N coupling Reactions Employing Borrowing Hydrogen Strategy

Kuhali Das and Biplab Maji*
Department of Chemical Sciences, Indian Institute of Science Education and Research Kolkata, Mohanpur 741246, India
kd17rs042@iiserkol.ac.in, bm@iiserkol.ac.in

The development of methodology prioritizes the sustainable synthesis of complex organic molecules in a greener and atom economical way. In this regard, the organometallic complexes are fruitful in the way it can catalyze the synthesis of high value-added chemical feedstocks. In the recent past, indeed, noble metal based complexes have shown significant progress in this field. But due to the low availability and high cost of noble metal complexes, homogeneous catalysis needed a savior. In this regard, the Earth's abundant first-row transition metal complexes of Cu, Fe, Co, Ni have shown comparable reactivity as those of noble metals. Manganese being the third most abundant transition metal in the Earth's crust is a crucial substituent than its higher congeners. In past four years, significant advancement has been achieved in the field of hydrogenation, dehydrogenation, and hydrogen autotransfer reaction employing manganese pincer complexes. Based on the previous developments, we presently focus on synthesizing manganese pincer complexes from readily available and cheaper feedstock and their application in borrowing hydrogenation reactions. We have recently reported the SNN pincer manganese complexes for the stereoselective synthesis of (1+n) membered cycloalkanes from methyl ketones and 1,n-diols. Apart from the metal-ligand bifunctional behavior, the hemilability of the sulfur-containing sidearm is playing a crucial role in achieving the stereo-defined products. The catalysts developed also shown significant activity for the N-alkylation of aromatic amine derivatives and aza-Michael addition of amines to allylic alcohols. In most reactions, water is the sole byproduct paving the pathway to greener synthesis.

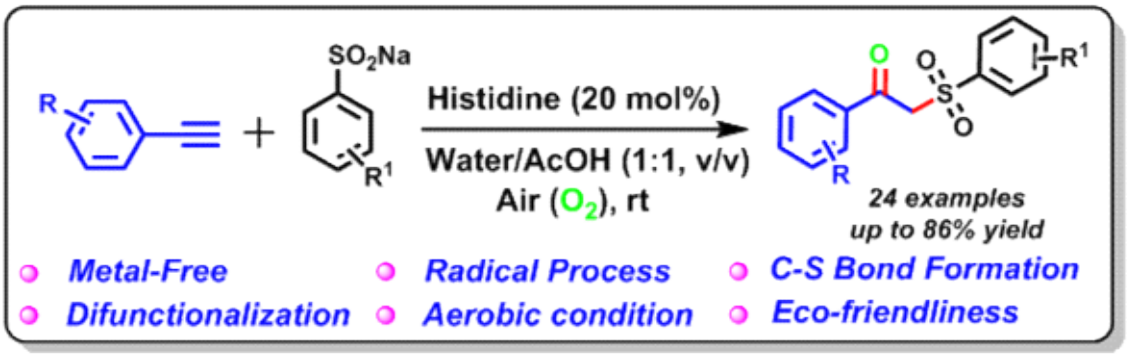
An efficient amino acid-catalyzed protocol for the synthesis of β-ketosulfones using terminal alkynes and arylsulfinic acid sodium salts under aerobic conditions in water/AcOH has been developed. This reaction involves an in situ generated vinyl radical intermediate and an atom transfer radical addition (ATRA) process via oxygen capture to form the desired products in good to excellent yields. This protocol is operationally simple and environmentally friendly and proceeds under very mild conditions.



Scheme: Amino acid-catalyzed direct synthesis of β-ketosulfonesviadifunctionalization of alkynes.

Keywords: Amino acid, Aerobic oxidation, Sulfones, Green approach, Metal-free.

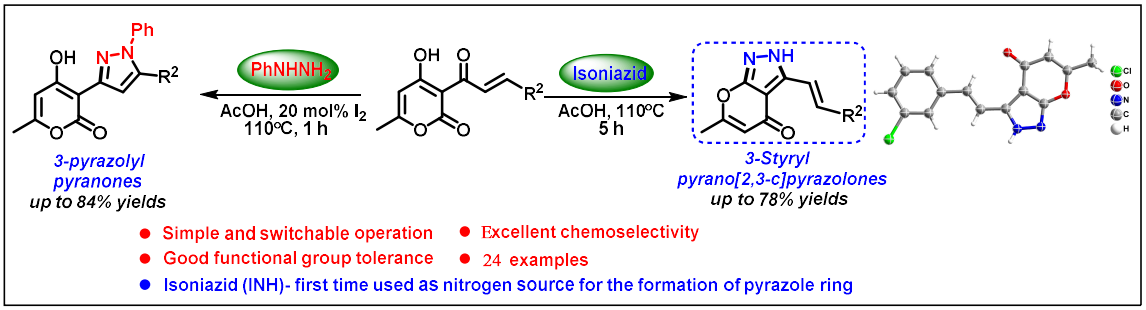
Tuning the Chemoselectivity of Dehydroacetic acid Derived Enones Enabled by Isoniazid and Phenylhydrazines: An Undivulged Efficient Access to 3-Styryl Pyrano[2,3-*c*]pyrazolones

Sumedha Swarnkar,[a] Mohd Yeshab Ansari,[a] and Atul Kumar*[a,b]
[a]Medicinaland Process Chemistry Division,CSIR-Central Drug Research Institute, Sector 10, Jankipuram Extension, Sitapur Road, Lucknow-226031, India
[b]Academy of Scientific and Innovative Research, New Delhi 110001, India.
E-mail: dratulsax@gmail.com ,sumedhaswarnkar@gmail.com

The first-time reported nitrogen source-based chemoselectivity of Dehydroacetic acid (DHA)-derived enones has been tuned by Isoniazid (INH), and phenylhydrazines respectively. When INH a first-line antitubercular drug, was employed as a new surrogate for nitrogen source, preferentially unconventional 1,3-dicarbonyl addition occurred, providing a series of fused 3-styryl pyrano [2,3-*c*] pyrazolones in good yields. While in the presence of phenylhydrazines and molecular iodine, the reaction was proceeded via oxidative annulation across enone framework, resulting in the efficient and straightforward access to 3-pyrazolyl pyranones.



Scheme: Strategy for the synthesis of pyrano[2,3-*c*] pyrazoles.

Base-promoted aza–Michael addition/intramolecular cascade cyclization betweenynones and 2–aminobenzonitriles: An assembly of multisubstituted 4–aminoquinolinederivatives

Ankit Kumar and Akhilesh K. Verma*
Synthetic Organic Chemistry Research Laboratory, Department of Chemistry,University of Delhi, Delhi 110007, India
E-mail-averma@acbr.du.ac.in

A Novel and efficient base–promoted one–pot reaction of ynones with 2–aminobezonitriles is described. The reaction initiated through sequential aza–Michael addition/intramolecular cascade cyclization to afford various multisubstituted 4–aminoquinolines and 4–amino[1,8]naphthyridines in good to excellent yields. Operational simplicity, high atom–economy with broad substrate scope makes this protocol more attractive. In addition, the gram–scale synthesis and further transformation of the product were studied. 2–Haloarylyones as substrate provide N–arylquinolones as sole product.

Synthesis, Characterization and Application of Chitosan-N-(4-hydroxyphenyl)-Methacrylamide Derivative for Drug Delivery System

Shefali Jaiswal[a]*, P.K.Dutta[a]& Santosh Kumar[b]
[a]Polymer Research Laboratory, Department of Chemistry, Motilal Nehru National Institute of Technology, Allahabad 211004, India
[b]Division of Chemical Engineering, Konkuk University, Seoul 05029, Republic of Korea
*Email: shefalijaiswalalld@gmail.com

The aim of this study was to synthesizeda novel CS modified N-(4-hydroxyphenyl)-methacrylamide (CSNHMA) via aza Michael addition reaction between CS and N-(4-hydroxyphenyl)-methacrylamide (NHMA) in ethanoland to evaluate its biomedical potential. The synthesized conjugate was characterizedby FT-IR, ^{1}H-NMR, XRD and FE-SEM analysis. The FTIR spectrum of CSNHMA hybrid showed the presence of the new absorptionpeak at 929 cm^{-1} and 1422 cm^{-1} for the out of plane C–H bending and C-C stretching vibrations of aromatic ring present in NHMA, respectively and the ^{1}H-NMR spectrum of CSNHMA showed a new characteristic signalappears around 8 ppm corresponding to the protons of phenyl group present in NHMAconfirming the successful incorporation of the NHMA into CS framework. The FE-SEM images of CSNHMA showed a highly porous network. Consequently, it uses was analyzed as a drug delivery carrier. For in vitro drug release study, we prepared CSNHMA NPs and curcumin loaded CSNHMA NPs with small size (<300 nm) and (< 240 nm) respectively viaionic gelation route andthe encapsulation efficiency of drug was found to be 77%.In vitro release studies demonstrated a faster and sustained release of curcuminloaded CSNHMA NPs at a pH 5.0 compared to physiological pH. These findingshowed that CSNHMA NPs havethe advantage of sustained drug release, suggesting that CSNHMA NPs can be used as a carrier of anticancer drugs.

From Equilibrium to Non-Equilibrium: Towards The Creation of Complex Living Catalyst

Ms. Antara Reja
Research Scholar, IISER Kolkata, India
antarareja13@gmail.com

How life was created from inanimate matter is still a mysterious and unanswered question but we know that three important parameters metabolism, replication and compartmentalization played an important role during evolution of life. Specifically, metabolism is considered as a heart of evolution composed of multiple cascades of bond formation and breaking that were critical for primitive evolution. Nature gradually chosehighly evolved and complex enzymes featuring binding pockets with precise arrangement of amino acids to efficiently foster such transformationswith remarkable selectivity of substrates. Here, in our first work, we have reported a lipidatedshort peptide which accesses homogenous nanotubular morphology to efficiently catalyze the C-C bond cleavage and formation. Our first catalyst was stable under thermodynamic equilibrium but most lifedistinguishingfeatures rely on non-equilibrium dynamics, involving constant energy dissipation, kinetic control, and are orchestrated through feedback loops. So, secondly, we have created a single amino acidbased catalyst through the self-assemblydriven by the substrate under out-of-equilibrium condition. Further, continuous supply of substrate was required to maintain the living state of the catalyst.

Catalytic Asymmetric Formal Total Syntheses of (+)- and (-) Cycloclavine

Dr. Saikat Chaudhuri
Postdoctoral Research Associate, University of Kalyani, India
vbsaikat@gmail.com

Clavine family of ergot alkaloids (Figure 1) has a long-lasting and significant impact on both human health as well as agriculture. They were first documented as notorious poisons, stemming from the Middle Ages in central Europe, where consumption of ergot alkaloid contaminated cereal grains led to epidemics of ergotism (also known as St. Anthony's fire) resulting in about ten thousands of fatalities.[1]

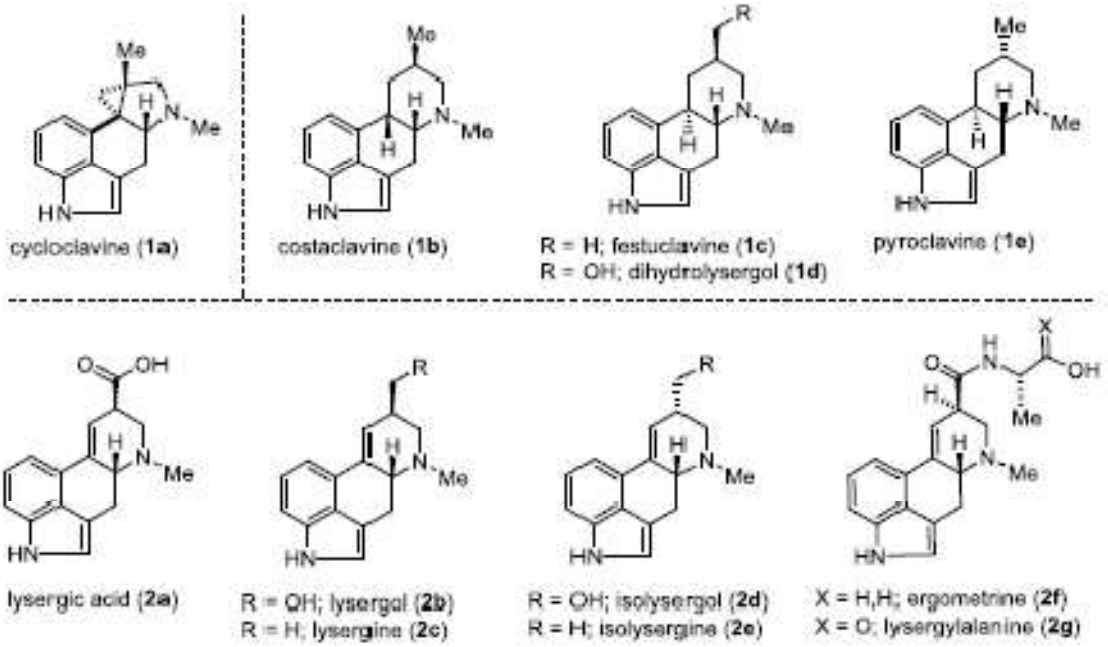

Figure. Selected clavine alkaloids (**1a-e**) and lysergine alkaloids (**2a-g**) of biological relevance.

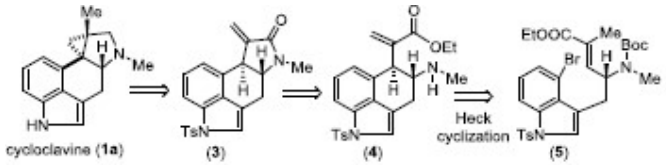
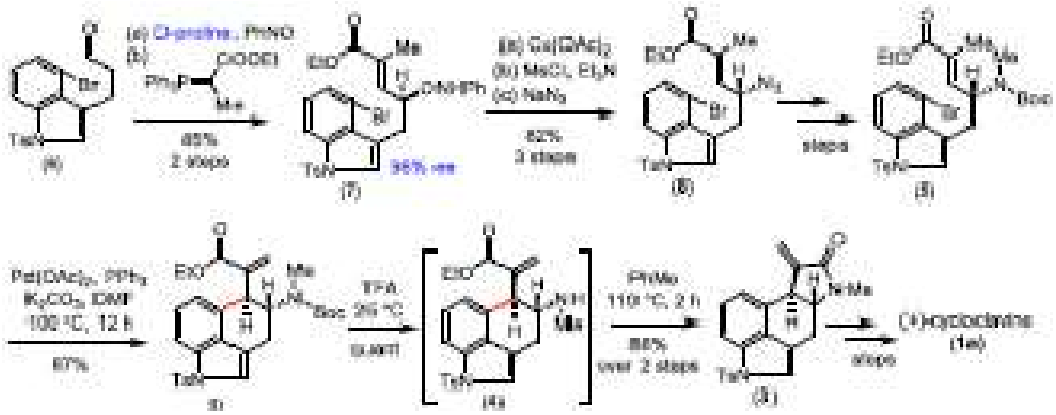
Most ergot alkaloid structures contain a tetracyclic ergoline ring system (**1b-e** and **2a-g**), except cycloclavine (**1a**), which is sharing a pentacyclic framework with a vicinal all-carbon quaternary streo centre.[2] Because of the varied and powerful biological activities of these alkaloids have long attracted the interests of synthetic chemists. We also elaborated the total syntheses some of the congener of this family.[3] In this talk I would like t o discuss one of my doctoral research work Catalytic asymmetric formal total syntheses of (+)- and (-) cycloclavine.[4]



Retrosynthetically, it was envisioned that cycloclavine (**1a**) can be synthesized from an advanced enantiopure intermediate α, β-unsaturated amide **3** (Scheme 1) via isomerisation followed by reduction of amide functionality and cyclopropanation. Compound **3** can be accessed from α, β -unsaturated ester **4**, which could be, in fact, common intermediate for clavine alkaloids shown in Scheme 1.



Scheme 2: Enantioselective formal synthesis of cycloclavine.

Towards this, 3-indolyl-propanaldehyde **6** was reacted under catalytic enantioselective α- oxyamination reaction with nitrosobenzene in the presence of 10 mol% D-proline (Scheme 3). This reaction afforded α-oxyaminated aldehyde intermediate, which was immediately reacted with a stabilized Wittig, prepared from 2-bromo ethylpropionate, to afford compound **7** in 85% over 2 steps and with 96% ee. With enantioenriched **7** in hand, formal total synthesis of cycloclavine was achieved following a key 5-*exo-trig* cyclization (Scheme2).

In conclusion a total synthesis of cycloclavine (**1a**) is already reported by Szántay and co-workers,[2c] this efforts culminated in formal total synthesis of naturally occurring cycloclavine (**1a**).

sweta.kamal123@gmail.com

The fundamental mechanism for nucleation during protein misfolding and aggregation under the unrestricted influence of environmental tormentors, especially pesticides is poorly explored. These toxicants could play a major role in the genesis of several pathogenic disorders. Certain reports have established the effect of environmental toxicants on misfolding of Intrinsically Disordered Proteins (IDPs) but their role on non-IDPs or metabolic proteins and their gain of toxicity is still elusive. To fill this lacuna, we hypothesized that the pesticides (e.g. Rotenone) as environmental toxicants may interact with metabolic proteins and lead to the generation of toxic conformers.

Size exclusion chromatography with LC-MS and 1D NMR studies shows the strong affinity of rotenone to Malic Dehydrogenase (MDH), further docking studies have shown the interaction site was interestingly overlapping with the co-factor binding site. Further, Structural studies reveal the prominent structural changes. The hydrophobic changes in secondary structure of MDH were analyzed with Bis-ANS. Circular dichroism showed structural alterations accompanied by the complete loss of alpha helices with an increase in disordered form. Rotenone also destabilized the protein and reduced the melting temperature by 3°C as detected by thermal unfolding analysis. Rotenone also interferes with spontaneous refolding of MDH, leading to the formation of toxic conformers. The cytotoxic effect of the conformers was established by the decrease in viability of SH-SY5Y cells (60% viability for 0.25μM seeds). Further study reveals the cytotoxic impact of misfolded MDH conformers associate with the induction of oxidative stress. The study has confirmed the binding of Rotenone induces the misfolded MDH conformers formation which are cytotoxic in nature.

Recent Advancement in The Design of Photoaffinity Chemical Probes for Protein And Its Application in Detecting Antibiotic Resistance

Monisha Singha*,[a]Anindya S. Ghosh,[b]and Amit Basak[a,c]
[a]Department of Chemistry; [b]Department of Biotechnology,[c]School of Bioscience; Indian Institute of Technology Kharagpur, Kharagpur 721302, India.
singhamonisha92@gmail.com

Photoaffinity-based chemical probes are powerful chemical tools for understanding complex biological systems through labeling and detection of disease-causingproteins in biomedical research, chemical proteomics and drug discovery. Designing these probes is an important issue as one needs to consider the desired biological potency, selectivity, and cell permeability of the probe. Conventional design of photoaffinity probe requires assembling of three components, namely selectivity hand also called reversible warhead, photoreactive hand and visualization hand on a template through linkers to provide the final molecular entity. This process is synthetically challenging and often the overall steric size of the probe restricts its applicability due to solubility problems in biocompatible solvents and poor cell permeability. To address these issues, a chronological improvement of the design technology of such small-molecule probes and the development of a sterically less demanding dual acting azido naphthalimide template have been achieved in our laboratory. In the current situation antibiotic resistance is the biggest threat to the modern medicine globally. The emergence of various classes of β-lactamases including the metallo-β-lactamases (class B-MBL) is the major cause for such resistance. Using the azido naphthalimide template we have designed affinity based fluorescent probesfor thedetection of New-Delhi-metallo-β-lactamases which renders carbapenems, one of the last-line of antibiotic, ineffective.The design, synthesis and the application of these probe

Pd-Catalysed Remotely C4-Functionalization of 2-aryl Benzoxazoles *via* Ortho C-H Activation of 2-Amido Phenol

Kanchanbala Sahoo and Niranjan Panda*
Department of Chemistry, National Institute of Technology Rourkela, Odisha-769008, India
kanchansahoob@gmail.com

2-aryl benzoxazoles are one of the most important heterocyclic compounds having tremendous biological activity [1]. Owing to the unique chromophoric property, 2-arylated benzoxazole are found in optical brighteners, blue LED, etc[2]. Furthermore, benzoxazoles are often used as potential ligands in transition metal catalysed coupling reactions [3]. A one-pot direct transformation to remotely C-H alkene functionalized 2-aryl benzoxazoles from the reaction of amidophenol and electronically deficient olefin was reported. Control experiments confirm that the Pd-catalyzed regioselective C−H activation/alkenylation occurs at the first step by leading to *ortho*-alkenylated amidophenol which subsequently underwent tandem intramolecular annulation to afford C4-alkenylated 2-arylbenzoxazole derivatives [4]. Fortunately, one-pot hydrolysis of C4-alkenylated benzoxazoles produced 8-hydroxy carbostyril which is used as a resourceful intermediate for the preparation of two powerful β2-adrenergic receptor agonists i.e., procaterol and indacaterol for the treatment of asthma. Followed by this work, we have developed a Pd-catalyzed method for the direct synthesis of C4-aryl benzoxazoles from 2- amidophenols. The reaction proceeds with anilide directed *ortho*-arylation, followed by acid- catalyzed cyclization. Deuterium exchange experiment suggests that under optimized reaction conditions, the directing potential of –NHCOPh group dominates over the –OH and arylation occurs exclusively adjacent to the amide group. Finally, a simple one-pot method has been developed to access strategically difficult 3-aryl-2-aminophenols from the hydrolysis of 2,4- diaryl benzoxazole in good yield[5].

Development of a Red Emissive Biocompatible Serum Albumin Carrier for Drug-Delivery Application

SubhajitGuria,[a]SusantaAdhikari*[a]
[a]Department of Chemistry, University of Calcutta, 92A.P.C. Road, Kolkata-700009, India
Email: adhikarisusanta@yahoo.com, subhajitguria28@gmail.com

The present world is under a constant burden from cancer, which is having an increasing trend in the number of cases, crippling the physical, emotional, and financial state of affected individuals and their families. Cancer can be treated either by surgery, chemotherapy, or with a combination of both. Theranostics is the combination of two terms: "Therapeutics" and "Diagnostics"[1] that allows for simultaneous diagnosis and targeted therapy with minimal side effects. Fluorescent molecules have found their importance in the field of medicinal chemistry and image-guided surgery. A chemotherapeutic drug endowed with fluorescence could serve as a beacon to visualize the event of drug delivery. However, many chemotherapeutic agents suffer from poor water solubility, low bioavailability, and non-specific distribution in the body tissues and organs, leading to serious side effects and toxicity and force the patient to discontinue the treatment. Significant attention has been given to resolve the issue by encapsulating the chemotherapeutic agent with biodegradable nanocarriers.[2]Herein, we have designed a red emissive serum albumin nanoparticle carrier (DFPACOH@BSA-NPs)[3] that encapsulates a hydrophobic drug thymoquinone (TQ), successfully deliver, and image the event of delivery in A549 cells. The anticancer property was further evaluated for TQDFPAC-OH@BSA-NPs by intracellular Reactive Oxygen Species (ROS) generation study.

Design and Development of a Series of Flexible Water-Soluble Ferrocenylquinoline-Based Preclinical Drug Candidates targeting LeishmaniaDonovani

Tanushree Mishra, Susanta Adhikari*
Department of Chemistry, University of Calcutta, 92, A.P.C. Road, Kolkata-700009, India.
mrs.tanu123@gmail.com, adhikarisusanta@yahoo.com

Visceral leishmaniasis (VL), or kala-azar, is a life-threating diseaseand is considered to be a major health problem in developing countries.The emergence of resistance against antileishmanial drugs incurrent use necessitates the search for new classes of antileishmanialcompounds.Herein, we havedeveloped a series of water-soluble ferrocenylquinoline derivativesfor targeting Leishmaniadonovani. Among them **CQFC1** showed the highest efficacy in comparison to other drugs, in use or used both in oral and intramuscular routes. In this study we aimed to exploit the quinoline as well as ferrocene nucleus for the development of a novel antileishmanial compound with minimal toxicity and greater antileishmanial efficacy. The newly modified drug did not induce any toxicity to splenocytes and on hematopoiesis, induced protective cytokines, and did not hamper the drug-metabolizing enzymes in hosts. It acts through the reduction and the inhibition of parasites' survival enzyme trypanothionereductase of replicating amastigotes in hosts' reticuloendothelialtissues.Unlike conventional drugs, this molecule did not induce the resistance-conferring genes in laboratory-maintained resistant L. donovani lines. Experimentally, this easily bioavailable preclinical drug candidate overcame all of the limitations causing the discontinuation of the other conventional antileishmanial drugs and we hope this will open up a convenient route for the treatment ofLeishmeniaDonovani.

The synthesis of amide is an elegant transformation in synthetic organic chemistry and molecules having amide linkage arewidely distributed in the field of pharmaceuticals, natural products and agrochemical industries. Generally, amides are preparedusing carboxylic acid derivatives and amines or by Beckmann rearrangement. However, several limitations are associated with these protocols such as strong acidic media, use of additives, longer reaction time, harsh reaction conditions, use of toxic metals, tedious purification process andlow functional group tolerance. Herein, we describe mild, greener and the highly efficient Zn(II)-catalyzed direct synthesis of secondary amides from ketones using HOSA as the nitrogen source in aqueous media. [1]

saumyabhu19@gmail.com, jawaharbbau15@gmail.com

A conspicuous procedure for acid-catalyzed conversion of oxime intermediate to the amides is recognized as Beckmann Rearrangement. Although this is a prominent reaction, prerequisite of high reaction temperature and strongly acidic media at longer reaction time encumbers its applicability for acid-sensitive substrates (for eg. *N*-Boc, -COOR, -OH etc.). A literature study admits that there are limited methods available for the synthesis of secondary amides directly from ketones under mild reaction condition. In interest of this, herein we reported a copper catalyzed single step and mild synthesis of secondary amides from ketones using hydroxylamine-*O*-sulfonic acid (HOSA) as aminating agent and $Cs(OH).H_2O$ as base in TFE:DCM[1].

Synthesis of 'Dapsone-Phytochemical Conjugates Against Mycobacterium Leprae: A Potential and Cost-Effective Approach in Novel Drug Discovery using Obsolete Drugs and Natural Products

Shasank S. Swain
Division of Microbiology and NCDs, ICMR-Regional Medical Research Centre, Bhubaneswar, Odisha-751023, India;
swain.shasanksekhar86@gmail.com;

Leprosy continues to be the belligerent public health hazard for the causation of high disability and eventual morbidity cases with stable prevalence rates, even with treatment by the on-going WHO-recommended multidrug therapy (MDT). Indeed, dapsone (DDS) resistance by mutations in the target enzyme, dihydropteroate synthase (DHPS), has led to an increase in treatment failure from MDT. As a solution, obsolete DDS was reactive through chemical conjugation with five phytochemicals as 'dapsone-phytochemical conjugates' (DPCs), based on azo-coupling (R-N=N-R') reaction. The possible biological activity, mainly, antimycobacterial and antileprosy and toxicity profiles of proposed conjugates, was verified with several computational intelligence programs targeting both wild and mutant types of DHPS before synthesis. From vast bioinformatics and cheminformatics analyses confirmed that 'thymol-dapsone-thymol or DPC4' was the most potential candidate among all proposed conjugates. Later, synthesized all five DPCs in the desired laboratory conditions and spectral characterizations were done viz., proton-HNMR, FTIR, UV, and LC-MS study-cum-verification with suggested computational results. The *in vivo* antileprosy activity of DPCs was monitored with only available gold standard 'mouse-foot-pads (MFP) propagation method with WHO recommended concentration 0.01% mg/kg for three months. Afterward, the host-toxicity testing of the most active DPC4 was done with isolated cultured-human-lymphocytes *in vitro*. Remarkably among all conjugates, the DPC4 showed potential as only one-log bacilli cells in DDS-resistant and no bacilli cells were found in the DDS-sensitive *Mycobacterium leprae* infected mice-foot-pads. Simultaneously, the *in vitro* host-toxicity study also confirmed that the DCP4 up to the concentration of 5,000 mg/L level was safe for oral-administration since a minor number of dead cells were found in red color under a fluorescent microscope. Overall, the antioxidative and antimicrobial potency of thymol enhances the activity and reduces DDS's toxicity profile in conjugate form. Thus, evidence from *in vivo* antileprosy activity and *in vitro* host-toxicity study suggested that the DPC4 could be used in place of DDS in MDT after some pharmacological validation. Parallelly, this interdisciplinary inventive, cost-effective phytochemical conjugation drug development module could be a novel approach towards reactive-cum-reuse of obsolete/ clinically inactive drugs and utilization of more natural products in mainstream medicine-cum-sustainable nation-building program.

Keywords: Dapsone resistant *Mycobacterium leprae*; Dapsone-phytochemical conjugation; Mouse-foot-pad propagation method; Host-toxicity testing with cultured-human-lymphocytes.

Nickel-Catalyzed Cross-Coupling of Alkyl Carboxylic Acid Derivatives with Pyridinium Salts via C−N Bond Cleavage

Feba Thomas Pulikottil Ramadevi Pilli, Rohith Valavil Suku, and Ramesh Rasappan*
School of Chemistry, Indian Institute of Science Education and Research Thiruvananthapuram, Thiruvananthapuram, Kerala 695551, India.
*Ramesh Rasappan − School of Chemistry, Indian Institute of Science Education and Research Thiruvananthapuram, Thiruvananthapuram, Kerala 695551, India;
rr@iisertvm.ac.in

The transition metal-mediated cross-electrophile coupling *via* cleavage of $C(sp^3)$–N bonds to offer unsymmetrical diakyl ketones from various alkyl pyridnium salts and acyl chlorides was developed.[1] $NiBr_2 \cdot bpy$ catalyst, cosolvent system CH_3CN:DMA and Mn as reductant was the optimized condition. In substrate scope apart from 1^o, 2^o and 3^o acid chlorides, carboxylic acids were also employed as acylating agents which enabled the incorporation of acid-sensitive functional groups such as MOM, BOC and acetal to offer the acylated products in good yields.

The mechanistic studies in the preceding Ni catalyzed cross-coupling suggests (i) sequential reduction and (ii) radical chain process as the two most probable pathways for the complete catalytic cycle. In sequential reduction (i) oxidative addition of acyl chloride takes place as the initial step and then subsequent generation of alkyl radical from the pyridinium salts with the aid of Mn reduced nickel species occurs. In radical chain process (ii) there is a generation of alkyl radical by the low valent nickel catalyst as the first step and thereafter oxidative addition of the acid chloride takes place. Eventually, it leads to alkyl radical recombination on to the nickel centre and reductive elimination to complete the catalytic cycle. The radical scavenger TEMPO and radical inhibitor 2,4-Dinitrochlorobenzene corroborate the presence of radical intermediate.

This protocol gains its attention by accommodating no additives, cheap bipyridine ligand, proceeds at rt and by synthesis of vital compounds.

Utilization of Reusable Pd NPs and NHC-Pd@MNPs for Denitrogenative Coupling and Regioselective Direct C2 Arylation of Indole, Benzothiophene and Benzofuran

Rajeev V. Hegde and Ramesh B. Dateer*
Centre for Nano and Material Sciences (CNMS), JAIN (Deemed-to-be University), Jain Global Campus, Bangalore-562112, India
h.rajeev@jainuniversity.ac.in, d.ramesh@jainuniversity.ac.in

The greener approach for the synthesis of biaryl using palladium nanoparticle (Pd–NPs) catalyzed denitrogenative coupling between aryl hydrazine and aryl halides under ligand-free condition is established and on the other hand regioselective C2 arylation of indoles, benzothiophene and benzofuran without directing group has been accomplished using economically cheap Pd NPs and NHC-Pd@MNPs catalyst has been described. The phytochemicals of the black pepper extract plays a dual role in reduction of Pd^{II} to Pd^{0} and acts as stabilizing agent for Pd–NPs. The reusability of the catalyst is studied up to five cycles and a gram-scale synthesis has been achieved in both reactions. The reaction mechanism is well supported by control experiments and literature precedents, turnover number and turnover frequency studied.

Enhancement of angiogenin inhibition by polyphenol capped gold nanoparticles

Atashi Panda[a], Soumya De[b], Swagata Dasgupta*[a]
[a]Department of Chemistry, Indian Institute of Technology Kharagpur, Kharagpur 721302. India
[b]School of Bioscience, Indian Institute of Technology Kharagpur, Kharagpur 721302. India
atashipanda@gmail.com,

Angiogenin (Ang), a potent blood vessel inducerand its involvement in vascularisation makes it a potential target for the identification of the compound to inhibit its ribonucleolytic as well as angiogenic activity. Gallate containing moieties of green tea polyphenols (GTPs) have shown anti ribonucleolytic activity and the efficiency increases when gold nanoparticles serves as vehicle for the transport of GTPs.The inhibitory property of the ligands, was investigated using various spectroscopic techniques.Polyphenol conjugated gold nanoparticles were found to bind 10^2 times more strongly to the protein compared to only the polyphenols. UV-Vis kinetic studies determined the mode of binding of the polyphenols to be non-competitive in nature whereas that of polyphenol capped gold nanoparticles show a competitive mode of inhibition. This enhances its potential as an antiangiogenic drug, where the effect on angiogenesis of various samples was assessed by CAM assay. The polyphenol capped gold nanoparticles inhibit Ang with greater potency compared to the bare polyphenols and the presence of the gallate moiety significantly enhances the ribonucleolytic inhibitory potential. This structural aspect can be exploited for further studies in the development of antiangiogenic compounds based on natural polyphenols.

Self-Assembling Short-Peptide Conjugates Nanostructures: A Forward Step against Antibiotic Resistant Crises

Ramesh Singh and Khashti Ballabh Joshi*
Dr Harisingh Gour Central University Sagar, MP, 470003, India
rameshsinghchilwal@gmail.com

Multidrug resistant (MDR) or multi-antibiotic resistance (MAR) has become a global life-threatening problem of the current century. Such resistance has been found against every antibiotic that is potentiated and propagated by antibiotic-tolerant microbial biofilm and affecting every medical, industrial and agricultural sector. Therefore there is a dire need for novel antibiotics. Antibiotic development has reached its perfections in Nature with antimicrobial peptides (AMPs), most of which have broad-spectrum activity with very little resistance. Therefore our group has developed novel short-peptides based self-assembling nanomaterials with a new intrinsic property that can work as efficient antimicrobial agents' hence better alternatives during this antibiotic resistant crisis. In this talk, we aim to discuss short peptide based novel antimicrobial nanoformulations and nanomaterials such as lipidatedtripeptide and H_2S-responsive tripeptides nanostructures. We have used plethora of biophysical techniques to obtain a molecular understanding of these peptide structures and interactions within polymer, lipid and metal nanoassemblies. Such strategy will reveal their potential for application in medicine and industry to combat antibiotic resistance.

Endogenous Stimuli-Responsive theranostics for "activatable" image-guided combination therapy

Dr Moumita Gangopadhyay*
*Assistant Professor, Department of Chemistry, Ghatal Rabindra Satabarsiki Mahavidyalaya, Ghatal, Paschim Medinipur 721212, West Bengal, India,
orgchemist87@gmail.com

Combining two or more treatment modalities has been proved to be successful therapeutic approaches for cancer eradication.[1] The different treatment modalities follow separate mechanisms of attack against the tumor cells, affecting cell destruction to a large extent. Combinations of treatment modalities, such as photodynamic therapy (PDT) with photothermal therapy (PTT), PDT with chemotherapy, or PTT with chemotherapy, have been well explored till date[2-5]; however, in most of these cases, two or more different drugs have been utilized for the different therapies. This causes undesired side effects and reduces the efficiency of the treatment. Moreover, such multimodal therapeutics are always in their "active" forms for annihilating cancer cells, leading to undesired interactions[6] with different physiological elements in its path to the respective tumor cell. For an anti-cancer therapeutic to be effective, it must be site-specific to avoid any damage to healthy tissues. In view of this, the heterogeneous medium of cancer cells, unlike healthy cells, has been exploited extensively.[7] Therefore, different endogenous stimuli, viz. intracellular pH, intracellular hypoxia, specific enzymes, etc., have been utilized as tools to activate the therapeutic specifically in tumor cells, leaving healthy cells unaffected.[8] To facilitate real-time monitoring of such localized multimodal therapies, the therapeutic compound has been designed to exhibit different luminescence behaviors in cancer cells and in normal cells. Such selectively "activatable" theranostic compounds showed superiority over traditional anti-cancer treatments, in terms of site-specific cancer treatment.

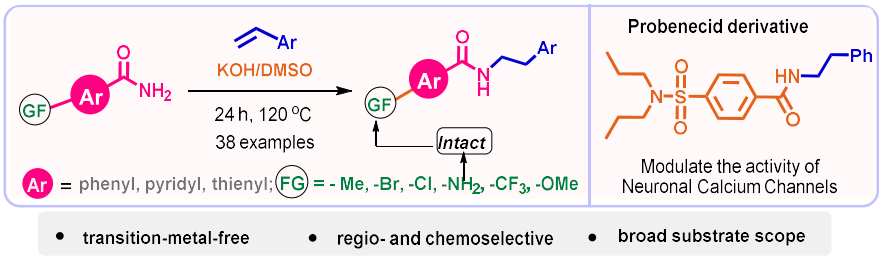
ayusheesingh27@yahoo.in



We report here a base-promoted protocol for the intermolecular anti-Markovnikov hydroamidation of vinyl arenes with arylamides to furnish the arylethylbenzamides with excellent chemo- and regioselectivity. The reaction tolerates a wide variety of functional groups which has been successfully extended with electronically varied handles, aminobenzamides, electron-rich/electron-deficient heterocyclic amides, and vinyl arenes to afford the hydroamidated products. Excellent chemoselectivity was observed for the amide group over amine. The proposed mechanism and significant role of the solvent was well supported by deuterium labelling studies and control experiments.

1,2-Disubstituted Benzimidazoles : Selective Synthesis and Molecular Docking Studies

Nusrat Sahiba[a], and Shikha Agarwal[a]*
[a]Department of Chemistry, Synthetic Organic Chemistry Laboratory, MLSU, Udaipur, India 313001
E-mail: shikhaagarwal@mlsu.ac.in, sahibanusrat786@gmail.com

A greener, facile, and scalable mechanochemical protocol has been developed from easily available substrate aromatic aldehydes and o-phenylenediamine using urea nitrate catalyst to afford 1,2-disubstituted benzimidazoles within minutes. The highly efficient urea nitrate catalyzed synthesis proceeded *via* carbonyl activation-cyclization-atmospheric oxidation pathway. Present methodology exhibited several advantages like solvent free synthesis, easy preparation of catalyst, recyclable catalyst, easy isolation, short reaction time, and excellent yields at ambient temperature. Green chemistry matrix of synthesized compounds revealed high atom-economy (90.74%), high reaction mass efficiency (89.9%),low e-factor(0.11),and excellent eco-score (78.5%).The molecular docking study of all the synthesized compounds for antibacterial and centromere associated protesin inhibitor activity gave potential hits *via* presence of high interaction pattern. Compound demonstrated -26.7009kJ/mol and -25.0285kJ/mol highest docking score with the selected 2XCS and 1T5C proteins, respectively.

AP-4

Green Synthesis of 5-Chloro-2-arylbenzo[d]thiazole Derivatives using Grindstone Technique through C-N and C-S Bond Formation

Ayushi Sethiya and Shikha Agarwal*
Synthetic Organic Chemistry Lab, Department of Chemistry,
Mohan Lal Sukhadia University, Udaipur, 313001, Rajasthan
ayushisethiya92@gmail.com, shikhaagarwal@mlsu.ac.in

An array of substituted 5-Chloro-2-arylbenzo[d]thiazoles was synthesized using 4-chloro-2-aminothiophenol and aromatic aldehydes in the presence of catalytic amount of urea nitrate under mechano-chemical grind stone technique. The designing of biologically active scaffolds and lead compounds using green protocols by minimizing the pollution and adverse impact on the environment is inevitable. Therefore, this pathway was successfully carried out under metal-free conditions in mild reaction condition and the desired products were obtained in high to excellent yields in short reaction time (30-60 sec) to avoid the adverse impact on the environment. The structural characterization of all the synthesized analogs was established by techniques like FT-IR, ^{1}H, and ^{13}C NMR sepctroscopy. The designed pathway has several advantages like eco-friendly, easy workup, high yields, solvent-free, and recyclability of catalyst. The urea was reusable at least four times for the further synthesis of catalyst without significant loss of activity. The high functional group tolerance with a variety of derivatives has been established. In this study we have established a highly promising approach for the synthesis of 5-Chloro-2-arylbenzo[d]thiazoles derivatives.

AP-5

Advancements in Synthetic Approaches of Bisdimedones

Pankaj Teli and Shikha Agarwal*
Synthetic Organic Chemistry Laboratory, Department of Chemistry, Mohanlal Sukhadia University, Udaipur-313001 (Raj.)
pankajteli802@gmail.com, shikhaagarwal@mlsu.ac.in

Bis-cyclic molecules are designed by attachment of two cyclic moieties around various linkers such as alkynic, aliphatic, olefinic and aromatic intermediate molecules. The presence of two cyclic moieties together in the same molecule either symmetrically or non-symmetrically influences the biological profiles of the resultant bis-cyclic molecules. Among bis-cyclic moieties, bisdimedones have emerged as an important and versatile moiety in the field of synthetic and medicinal chemistry. They are screened as precursors for the synthesis of several heterocycles such as acridinediones, xanthenediones, thioxanthenes and benzopyrans that exhibit immense pharmacological as well as industrial applications. Its extensive characteristics have attracted the scientists to develop various protocols for its synthesis from the reaction of dimedone with several aldehydes under different environmental conditions using various types of catalysts. This article encapsulates the recent progress in the synthesis of bisdimedone derivatives under several reaction protocols such as use of nanoparticles, ionic liquids, metal salts, simple organic compounds, and catalyst-free conditions etc. in the last 20 years.

Enhancing the properties of the film of the cataractous eye protein isolate (CEPI)

Prasun Chowdhury, Swagata Dasgupta*
Department of Chemistry, Indian Institute of Technology Kharagpur, Kharagpur 721302. India
Email: mail2praschow.25@gmail.com

Thin films prepared from protein sources arebiodegradability, biocompatibilityand finds application as a biomaterial for corneal tissue engineering; slow-release drug carrier for skin treatment in burns, ulcers or infected wounds. Cataract eye lens containing high protein concentration are discarded after surgery. Protein from discarded cataract eye lens can be extracted and be used to form biodegradable films having potential to be used as a material for drug delivery. To further enhance the mechanical property of the films, cross-linking of the proteins is done using varying concentrations of 1-ethyl-3-(3-dimethylaminopropyl) carbodiimide (EDC) in presence of NHS (N-hydroxysuccinimide). It significantly reduces the water solubility of the films.

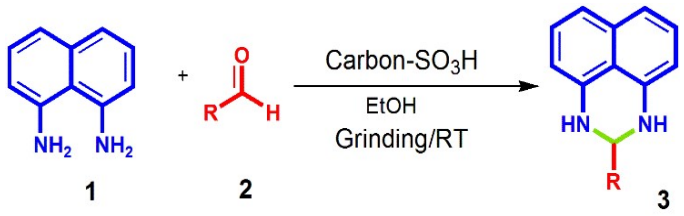
Click Chemistry Inspired Green and Mechanochemical Synthesis of Perimidines

Shikha Agarwal*
Synthetic Organic Chemistry Laboratory, Department of Chemistry, MLSU, Udaipur (Raj.), 313001, India
*shikhaagarwal@mlsu.ac.in

Catalysis is always known as a straightforward, sustainable and economical process for the formation of heterocycles and generation of C-N bonds. In the past few years, SO_3H functionalized carbon materials are a new addition to solid Bronsted acid catalysts, owing to its special characteristics like low cost and high Bronsted acidity. A new and scalable mechanochemical approach has been developed for the synthesis of perimidine derivatives using a highly efficient and recyclable carbon based sulfonic acid catalyst under metal-free conditions. A wide variety of aldehydes displayed cyclo-condensation reaction with 1,8-diaminonaphthalene in EtOH under ambient reaction conditions *via* grind-stone technique to produce substituted perimidines in excellent yields in a very short reaction time. This method has interesting features like single-step synthesis, high functional group tolerance, transition-metal free synthesis, high atom-economy, recyclable catalyst, no-need of tedious purification process, high green chemistry matrix (Eco-score and E-factor) that make this protocol green and eco-friendly.



Keywords: Solid acid catalysis, Click chemistry, Grind-stone method, Green chemistry, N-heterocycles, Perimidine

Study on Inhibtion of Mineralization of Urinary Calcium Oxalate Stone by Sodium Pyrophosphate

Nilam Kumari[1]. Dr. Naresh Kumar[2]
[1]M.SC Ph.D scholar, Department of Chemistry, B. N. Mandal University, Madhepura, Bihar-852113
[2]Professor**,** Department of Chemistry, B. N. Mandal University, Madhepura, Bihar-852113
nilam.nkd@gmail.com,drnareshchem@gmail.com

Biological importance of sodium pyrophosphatealso to understand its applicability as inhibitors in urolithiasis, we have presently studied the inhibition efficiency of sodium pyrophosphate towards the mineralization of urinary stone forming minerals *viz.*, calcium oxalate, in aqueous as well as urinary media. An attempt has been made to unfold, tentatively, the mechanism of inhibition by this inhibitor. **Methods:** It was Observational experiment. The Studywas Conducted in the chemistry lab of university department of chemistry, B N Mandal University, Madhepura, Period between January 2019- June 2019 An experimental model was designed with the salt forming solutions, the whole operation took about 40 min. At the end the contents of beaker were digested in a hot water bath for 10 min, cooled to room temperature and centrifuged in small volumes. The total centrifugate was collected. Next oxalate content of the centrifugate of calcium oxalate mineralization experiments were determined.

Result: sodium pyrophosphate has a moderate inhibition efficiency towards calcium oxalate mineralization. At 0.05 M concentration, sodium pyrophosphate has a net inhibition of 30 % which is 26.65 % more than that of water (blank). Compared to water the percentage inhibition increased by 795.52%. With decreasing concentrations of sodium pyrophosphate, the centrifuge efficiency decreases. At very low concentration (0.01 M) its inhibition is only slightly higher than that of water. In urinary medium sodium pyrophosphate seems to function as a better inhibitor of oxalate mineralization. At 0.05 M concentration, sodium pyrophosphate has a net inhibition of 89.22 % which is 75.36 % more than that of urine.

Conclusion: it is observed that sodium pyrophosphate solution, under different concentrations, exhibits moderate to good efficiency of inhibition towards mineralization of urinary stone forming minerals *viz.*, calcium oxalate in aqueous as well as urinary milieu.

Key words: Urolithiasis, sodium pyrophosphate, centrifuge, inhibition

skbthakur@yahoo.co.in,

The attention of chemists towards thiazole derivatives is due to their antiviral, antimalarial, hypertension, HIV infection, and hypnotics properties and because they are new inhibitors of bacterial DNA gyrase B. 2-Aminothiazoles are versatile intermediates for highly functionalized heterocycles of widespread pharmaceutical use. Thiazole analogs exhibit the possible core skeletons of A3 receptor antagonists with moderate affinity and selectivity. A3 receptor antagonists are associated with the treatment of glaucoma. The thiazolo[3,2-*a*] pyrimidine ring system established a lot of attention in the literature mainly because of interesting biological properties associated with this ring system. These compounds are reported to possess antimicrobial, anti-inflammatory, antitumor, and immunomodulatory activities. The arylidinemalononitriles are versatile intermediates for the synthesis of a large number of biologically important heterocyclic molecules. Many of these derivatives are playing continually expanding roles in the development of different areas of chemistry, industry, pharmacology, and medicines. The diverse and interesting biological activities of thiazolo pyrimidine ring system led us to synthesize some novel 3,5-diphenyl-7-amino[1,3]-thiazolo[3,2-a]pyrimidine-6-nitrile derivatives by refluxing 2-amino-4-phenyl-1,3-thiazole and arylidinemalononitrile in propanol using NaOH as catalyst. Various synthesized products were characterized by ^{1}H NMR, mass spectrometry (MS), infrared (IR), and elemental analysis. Antifungal activities of the synthesized compounds were done by testing against Rhizoctonia solani and Drechslera orazae, two fungal pathogens causing diseases on rice crops.

Controlled Ethanolic Fermentation Exposed To 2-Acetylaminofluorine

Sanjay Kumar Srivastava
Department of Chemistry, S.G.G.S College, Patna City, Patna (Bihar)

The efficacy of 2-acetylaminofluorine on controlled ethanolic fermentation with the yeast Saccharomyces cerevisiae NCIM-2012 has been assessed. It has been found that the mutagen 2 acetylaminofluorine under trial has stimulatory effect on controlled ethanolic fermentation with the yeast Saccharomyces cerevisiae NCIM-2012 and enhances the yield of ethanol to anextentor 6.74531% higher in comparison to control fermentor flasks, i.e., 7.20 ml/100ml. in 50 hrs of incubation period. 5.1 pH and 26"C temperature with 22% (w/v) molasses solution.

Keywords: Saccharomyces cerevisiae NCIM-2012, Molasses, ethanol, 2-acetylaminofluorinc

Tulasi Decreases Pathogenic Microorganisms from Water

***[1]Dr.Pavani Peddi, [2]Dr.N.Usha Rani, [3]S.Lakshmi Tulasi**

[1,2,3]Assistant Professor Dept. of Chemistry, PVP Siddhartha Institute of Technology,Kanuru, Vijayawada, India.

*Pavanipeddi7@gmail.com

The Ocimum sanctum is a natural plant having antimicrobial movement against a large number of the microorganisms and in Ayurveda, In my childhood days my grandmother cured some infections with tulasi leaf extracts, tulasi lead extract is used to treat blocked nose and throat infection are cured by chewing of fresh tulasi leafs. It's my great memory with my grandmother. Tulsi used as antiasthmatic drugs. It is also used in treatment of fever, bronchitis, arthritis etc. The current investigation was centeredaround assessment of antimicrobial movement of Ocimum sanctum leaf remove in ordinary tap water and river water. The antimicrobial impact was concentrated with distinctive focus (300 to 600 mg L^{-1}) of Tulsi leaf separate in tap. In this, 600 mg L^{-1} grouping of plant removes treated water demonstrated successful antimicrobial action at 15 to 16 hrs. The Minimum Bactericidal Concentration (MBC) was seen in 600 mg L^{-1} remove fixation. The centralization of the bacterial cells restrained progressively for an hour was concentrated by spread plate technique.

Oligofurostanosides-Furostanol Saponins from *Asparagus filicinus* Buch-Ham. Fruits from Himachal Pradesh

N.K.Thakur
Department of chemistry, Baba Balak Nath College Chakmoh, Dist. Hamirpur, (HP), India. Pin 176039
dr.naresh.thakur@gmail.com

Asparagus filicinus Buch-Ham.(Family-Liliaceae) commonly called *'Saunspaur'*and *'Sensarpal'*, a wild growing plant of Himachal Pradesh and Punjab, has been taken for chemical studies due to its medicinal values.

The methanol extracts of fresh fruits of *Asparagus filicinus Buch-Ham*. on purification and chromatographic separation has been found to contain a complex mixture of steroidal saponins, out of which two new oligofurostanosides, **Filicinoside-E(1)&F(2)** have been isolated. Filicinoside-E &F, positive to Ehrlich reagent, could not be separated by CC. Acid hydrolysis of this mixture gave an aglycone -Diosgenin which was further confirmed by chemical and spectral techniques. The aqueous hydrolysate on usual work up revealed the presence of D-galactose, D-glucose and D-xylose. Further, on the basis of spectral (FAB-MS,^{13}C-NMR, IR) and chemical studies (permethylation, methanolysis followed by hydrolysis, Kiliani hydrolysis) **Filicinoside-E(1)&Filicinoside-F(2)** have been assigned structures as: 3-O-[{ β-D-galactopyranosyl (*1* →4)}{β-D-xylopyranosyl (1→6) }-β-D-glucopyranosyl (1→4)-β-D-glucopyranosyl]-26-O-β-D-glucopyranosyl-22α-methoxy- (25R)-furost-5-en,3β, 26-diol (Filicinoside-E) and 3-O-[{ β-D-galactopyranosyl (1→4)}{β-D-xylopyranosyl (1→6) }-β-D-glucopyranosyl (1→4)-β-D-glucopyranosyl] -26-O-β-D-glucopyranosyl- (25R)-furost-5-en,3β,22α, 26-triol (Filicinoside-F).

Studies on Structural and Spectral Investigation of Substituted Benzoins using DFT studies

Dr.B.Thanuja
Assistant Professor, Department of Chemistry, Sri Sairam Engineering College, Tambaram, Chennai
thanuja.che@sairam.edu.in

4-methoxy benzoin and 2-chloro-4-methoxy benzoin synthesized by crossed benzoin condensation and characterization done using FT-IR, UV-VIS spectra and structures were confirmed using single crystal XRD studies. The optimized molecular structure of the title compound were calculated using Density Functional Theory (DFT/B3LYP)/6-31G (d,p) basis set. The calculated geometric parameters were in good agreement with the experimental data obtained from our reported X-ay structure. The charge transfers in the molecules proved using calculated HOMO-LUMO energies.

OP-8

An Efficient Solvent-Free Synthesis of 3,4-Disubstituted Isoxazole-5(4h)-Ones Using Microwave Irradiation

Pramod Kulkarnia*
Postgraduate centre in Organic Chemistry and Department of Chemistry, Hutatma Rajguru Mahavidyalaya, Rajgurunagar, Pune-410505
pramodskulkarni3@gmail.com

Isoxazoles, a privileged class of five-member nitrogen and oxygen-containing heterocycles, conquer reputation in organic chemistry for their wide applications in pharmaceuticals, biologically active molecules, advanced organic materials, and as intermediates in organic synthesis. Most of the reported methods for the synthesis of these compounds suffer from disadvantages, including the use of toxic or odorous, expensive catalysts, catalyst preparation required, strong acid or base catalysts, use of organic solvent, tedious work-up procedures, troublesome waste discarding, two step procedure, long reaction times, and low yields. Hence there is scope to develop new methods for the synthesis of this molecule.

I have reported one-pot and three-component synthesis of 3-mehyl-4-arylmethyleneisoxazol-5(4H)-ones using microwave radiation under the solvent-free conditions, in the presence of potassium bromide as the catalyst. The method has given the products in high yields and short reaction times with an easy work-up process. The present method provides an easy and efficient approach for the synthesis of this class of compounds, because of its clean reaction profile and operational simplicity.

OP-9

A balance between Free Radicals and Antioxidants in Homoeopathy Treatment

Md. Mobashshir Sulaiman[1], Dr. Aftab Ahmad Sulaiman[2]
[1](B.Sc. Chemistry from Oriental College Patna City, Patna, Patliputra University), e-mail-mobashshirsulaiman087@gmail.com,
[2](Assistant Professor Engg. Chemistry School of Technology Maulana Azad National Urdu University(A Central University), Hyderabad Satellite Campus Darbhanga), aftabsulaiman@gmail.com,

In chemistry there has been a great deal of attention toward the field of free radicals, radicals and free electron and assist the drug action in homoeopathy treatment. A balance between free radicals and antioxidants is necessary for proper physiological function. Free radicals weakens the body's abilityto regulate them, a condition known as oxidative stress. Free radicals thus adversely alter lipids, proteins, and DNA and trigger a number of human diseases. Hence some times application of external source of antioxidants can assist in coping free radicals and oxidative stress. The present review provides a brief overview on free radicals and oxidative stress which cause cellular damages and the role of free electron, radicals as antioxidants in homoeopathy in the management of free radicals in human diseases.

Keywords: antioxidant, free radicals, oxidative stress

ss.saha@ictmumbai.edu.in

Designing chiral AIEgens without any externally tagged AIE active molecules to the chiral scaffold remains a long-standing challenge to the scientific community.[1-3] The inherent ACQ phenomenon associated with the axially chiral (R)-BINOL scaffold, together with the marginal Stokes shift limits their application as chiral AIE active materials. Herein, in our effort to design chiral luminogens, we have come across a design strategy where 2-phenacyl furans[4] when appropriately fused with the BINOL scaffold will generate solid-state emissive materials with high thermal and photostability stability as well as color tunable property**.** The structures were fully characterized and thermal stabilities, electronic properties, photophysical and electrochemical properties were systematically investigated. The unique twist in the molecules as evident from their X-ray crystal structure along with the short intermolecular interactions ameliorates the structural rigidification and restricts the detrimental π-π stacking interactions, restricting the internal rotations (RIR) accompanied by curbing the ICT process, resulting in the enhanced emission in the aggregated state The excellent biocompatibility together with high fluorescence quantum yield and large Stokes shift of one of the luminogen stimulated us to investigate its cell-imaging potential. The luminogen was observed well internalized and uniformly dispersed within the cytoplasm of MDA-MB-231 cancer cellswith high fluorescence intensity.

Photocatalyst-Free Visible Light Mediated Synthesis of Stilbenes From Cinnamic Acids and Arylazosulfones

Ruchi Chawla and P. K. Dutta
Department of Chemistry, Motilal Nehru National Institute of Technology Allahabad, Prayagraj 211004
ruchawlaoct@gmail.com

Visible light driven decarboxylative cross-coupling reactions have transpired as an extremely resourceful tool for the construction of C-C and C-heteroatom bonds over the last few years. The approach is highly ecosustainable but relies on the use of expensive or degradable photocatalysts.One tactic to preclude the use of these external photosensitizers can be the replacement of these photocatalystswith a photoactive substrate or reagent.In this regard, arylazosulfones are interesting bench-stable photoactive compounds which can furnish arylradicals under visible light irradiation and havebeen used for the synthesis of many important scaffolds in the absence of any metal, photocatalyst or additives. However, stilbenes, which are widely recognized for their biological activity and synthetic utility, have never been synthesized from cinnamic acidsvia avisible light mediated pathway.In the present work, we have exploited the emerging dyedauxiliary group approachfor developing aphotocatalyst-free visible light mediated decarboxylative synthesis of trans-stilbenes from cinnamic acids and arylazosulfones.The decarboxylation process is facilitated by the use of a base Cs_2CO_3, air and KI. A number of cinnamic acids and arylazosulfones were compatible with the developed synthetic protocol. The experimental results establish that the reaction proceeds via a radical pathway.

Keywords: Visible light, photocatalyst-free, cinnamic acids, arylazosulfones, stilbenes

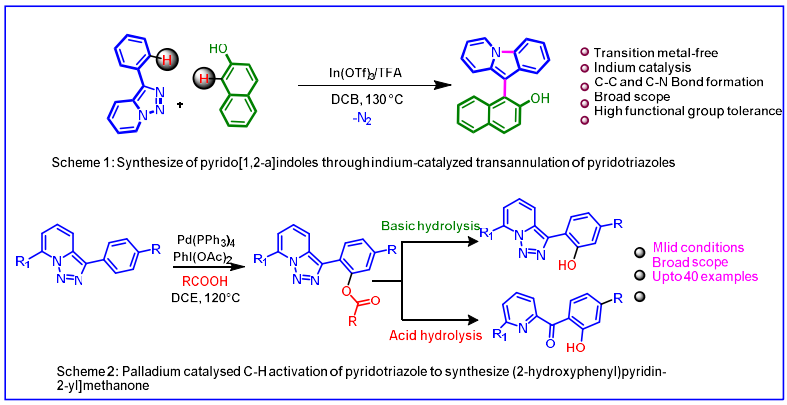
Ring Opening of Pyridotriazole for Synthesize N-heterocycles

Deepa Rawat, Dr. Subbarayappa Adimurthy*
Natural Products and Green Chemistry Division, Academy of Scientific and Innovative Research, CSIR-Central Salt and Marine Chemicals Research Institute, G. B. Marg, Bhavnagar-364002, Gujarat, India.
rawatdeepa145@gmail.com;adimurthy@csmcri.res.in

Nitrogen-fused heterocycles are key structural motifs found in material chemistry and medicinal chemistry.Trans annulation of pyridotriazoles is an extraordinarilyefficient and show excellent selectivity through *in-situ* generationof metal-carbenoid species and their reactions with different coupling partners transformed into a desired heterocycles.[1] Denitrogenative transannulation of pyridotriazoles offers anefficient method to obtain various heterocycles which are important intermediates in medicinal chemistry.[2,3] We have developed a convenient and efficient route to synthesize pyrido[1,2-a]indoles through indium-catalyzed transannulation of pyridotriazoles with different arenes and palladium-catalyzed direct *ortho* C–H acyloxylation of 3-phenyl-pyridotriazoles (Scheme 1).[4] The reaction was facilitated by $PhI(OAc)_2$ (PIDA) as an oxidant and with carboxylic acids as acyloxylation reagents followed by the hydrolysis yield the potential drug intermediates [(2-hydroxyphenyl)pyridin-2-yl]methanone (Scheme 2).[5]



Scheme 1: Synthesize of pyrido[1,2-a]indoles through indium-catalyzed transannulation of pyridotriazoles

Scheme 2: Palladium catalysed C-H activation of pyridotriazole to synthesize (2-hydroxyphenyl)pyridin-2-yl]methanone

Direct Transformation of Ketones into Secondary Amides *via* Beckmann Rearrangement using *O*-(Mesitylsulfonyl) Hydroxylamine (MSH)

Dinesh Chandra, Ajay K. Yadav, Saumya Verma, Puneet Kumar and Jawahar L. Jat*
Department of Chemistry, School of Physical & Decision Sciences, BabasahebBhimraoAmbedkar University (A Central University), Lucknow, UP, India-226025
dineshchm@gmail.com

The Beckmann rearrangement is a versatile method for the synthesis of secondary amides or lactams from ketoximes in the synthetic organic chemistry. Secondary amides are widely present in pharmaceuticals, bioactive natural products, polymers and agrochemicals, hence their synthesis is also important. Traditional Beckmann rearrangement requires harsh conditions (strong acid and high temperature) which impeded the applicability of this process towards the sensitive substrates. To overcome these limitations, we have developed a highly efficient method for the synthesis of secondary amides directly from ketones using *O*-(mesitylsulfonyl)-hydroxylamine. This reaction tolerates multiple functional groups, proceed rapidly at room temperature without any additive, and a simple basic aqueous work-up provide the products in excellent yield with high purity.[1-2]

Greener Synthesis of Curcumin Diimino Stabilized Silver Nanoparticles: Efficient Sustainable Catalyst for Nitroaromatics Reduction in Water with Bactericidal Properties

Nishi Gandha Gogoi, Jyotirekha G. Handique*
Department of Chemistry, Dibrugarh University, Dibrugarh-786004, Assam
ngogoi28@gmail.com

A green one step method of synthesizing silver nanoparticles stablized by curcumin derived diimino Schiff base is developed. Three curcumin diimino Schiff base prepared by a simple method from curcumin and 1,2-diaminoethane, 1,4-diaminobutane and 1,6-diaminohexane with improved aqueous solubilty compared to insoluble curcumin, were used as support in nanoformulation process. The stabilized silver nanoparticles were prepared in aqueous solution and at room temperature within 3 hours. These silver nanoparticles act as heterogenous sustainable catalyst in reduction of substituted nitroaromatics in aquous solution solution of sodium borohydride as reductant. Thus, the methodologies of silver nanoparticle synthesis and reduction of nitroaromtics is completed in water medium and so considered as eco-friendly. Secondly, both the support and stabilized silver nanoparticles showed bactericidal properties against bacterial strains (Staphylococcus aureus, Bacillus subtilis, Escherchia coli, and Pseudomonas aeruginosa).

Manganese-Catalyzed Electrochemical Tandem Azidation-Coarctate Reaction: Facile Access to 2-Azo-benzonitriles

Debabrata Maiti[‡], **Kingshuk Mahanty**[‡], **and Suman De Sarkar***
PhD Student, PhD Student at IISER Kolkata, India
dm15rs060@iiserkol.ac.in

Coarctate reactions belong to a specific class of concerted reactions those comprise a reactive center (coarctate atom) at which simultaneously two bonds are cleaved and two bonds are formed in a single step.[1] These versatile reactions exhibit broad applications for the construction of important carbo- and heterocyclic motifs via ring closing pathways.[2] Conversely, ring opening strategies privilege the access to several highly conjugated systems which are otherwise synthetically more challenging.[3].

Recently organo-electrochemistry has realized a renaissance for redox mediated transformations,[4] which has opened of a new platform in organic synthesis from its environment friendly and economic perspective. Herein, we report a successful implementation of the electro generated azide radical in C3–H azidation of various 2-*H*-indazoles and a follow-up fragmentation to access the conjugated 2-azo-benzonitrile derivatives. Advantageously, this undivided cell electrolysis proceeds under mediator and oxidant free condition at room temperature and under air which supports its sustainability.

Antimicrobial resistance has become a significant threat to global public health, thus precipitating an exigent need for new drugs with improved therapeutic efficacy. ADME fundamental pharmacokinetic properties useful for evaluation of the drugability of promising drug candidates. In the light of the above findings and of our former promising results with 1,2,3-triazoles as antibacterial agents.1-2 we undertook rational molecular design of novel antimicrobials in the class of organo phosphonate -1, 2, 3-triazole hybrids. The designed target compounds were initially submitted to Molinspiration, Molsoft and Osiris programs to predict their molecular properties that are important for drug candidates. The compounds showed moderate to good drug score 0.12.

Keywords: Molinspiration, Molsoft, Triazoles.

Non-Equilibrium Generation of Catalytic Proto Nucleobase Supramolecular polymers

Syed Pavel Afrose, Chiranjit Mahato and Dibyendu Das*
IISER Kolkata
spa17rs017@iiserkol.ac.in

Nature has developed nucleic acid polymers for crucial functions such as information transfer. The kinetically stable yet thermodynamically activated nature of the linkages hints towards their generation under a supply of energy, which also might have endowed them with properties such as catalysis, thereby facilitating the evolutionary pathway. Here we show the generation of supramolecular polymers of melamine, a possible proto-RNA building block driven by the addition of an activated monomer, an approach often seen in Nature in the form of generation of tubulins and actin polymers. Inspired from extant hairpin ribozyme, we utilize reversible covalent modification to install a catalytic imidazole moiety in the polymer backbone. This helps us achieve dissipation through hydrolysis, predominantly from the assembled state, resulting in disassembly and also creates a kinetic asymmetry in the cycle. Lack of dissipation on use of a non-catalytic analogue leads to polymers that are trapped in time. Interestingly, addition of a planar intercalating molecule increases the stability of the polymers, similar to what the midwives did during early evolution.

OP-18

Synthesis & Characterization of Benzothiazole Derivative Schiff Base Ligand with,Complex of Co(II)

Naresh Kumar Mirdha, Pawan Kumar & Dr. Naresh Kumar*
Research laboratory, Univ. Dept. of Chemistry
B. N. M. University, Madhepura, Bihar, (India)-8542113
E-mail: naresh.mirdh@gmail.com, drnareshchem@gmail.com

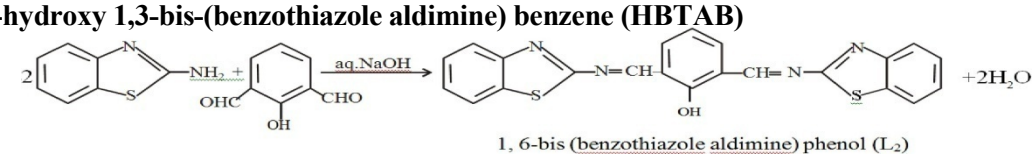
Organometallic compound and Schiff base complex are important area in modern science specially in biomedical science. Here Schiff base ligand and complex is most vital due to its widely usefulness. Benzothiazole & its derivatives play an important role in biological activities like anticancer agent, antidiabetic agent, anti- inflammatory agent, antimalarial agent etc. While its Schiff base also play an important role. As a metal complex of BT derivatives exhibited higher therapeutically value.

This paper deals with synthesis & characterization of BT Schiff base ligand & their Co (II) complex. Schiff base obtained shows very effective biological activities while complex of Co (II) is very much important for that very purpose.

Key words: Benzothiazole, 3-formyle benzaldehyde, ABT, Schiff Base, BTAB

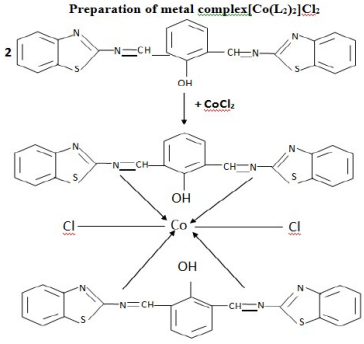
Synthesis of ligand-L

2-hydroxy 1,3-bis-(benzothiazole aldimine) benzene (HBTAB)



1, 6-bis (benzothiazole aldimine) phenol (L_2)

Bis-[2-hydroxy 1,3-bis-(benzothiazole aldimine) benzene]cobalt(II)chloride



[Co $(L)_2$] Cl_2Bis-[2-hydroxy 1, 3-bis-(benzothiazole aldimine) benzene]cobalt(II)chloride

Conclusion

All Co(II) complexes were found diamagnetic. Their electronic spectra did not show any d – d bands but were only dominated by charge transfer bands. The charge transfer band at 28, 455 – 28610 $cm^{-1}$was to t2g eg their possible tetrahedral environment.

Emergence of Enhanced Protometabolic Activity and Promiscuity via Dissipative Self Assembly

Sumit Pal, Antara Reja, Subhajit Bal and Dibyendu Das*
IISER Kolkata
spal822@gmail.com

In living systems, energy is consumed to fuel the metabolic networks of enzymatic reactions in conditions that are far from equilibrium. The emergence of metabolic pathways is intricately related to the evolutionary journey of modern enzyme with different theories suggesting retrograde evolution model to the early emergence of promiscuous enzymes. Herein, we report substrate driven non-equilibrium generation of catalytic machinery from a single amino acid functionalized fatty acid in presence of a cofactor hemin. The non-equilibrium assembled state showed acceleration of catalytic potential by degradation of the substrate and subsequently resulted in disassembly. Controls that promoted equilibration could not access the three-dimensional microphases and showed substantially lower catalytic activity. Significantly, the assembled state showed latent catalytic function that helped in the creation of the same substrate via hydrolysis of a precursor. Utilizing a promiscuous cascade, the assembly was benefitted with augmented lifetime of the catalytic state and thus promoted protometabolism. The results contribute towards our understanding of primitive promiscuous catalytic machineries that assisted the minimal metabolism of early life.

Spectral and Conformational Studies of Some Novel *N*-Acyl-Piperidin-4-One Oximes

K. Selvaraju

Department of Chemistry, Sri Sairam Engineering College,Chennai - 600 044, Tamil Nadu, India

selvaraju.che@sairam.edu.in

A collection of novel *N*-formyl-*t*(3)-methyl-r(2), *c*(6)-bis(2'-furyl)piperidin-4-one oxime **(1)**, *N*-acetyl-*t*(3)-methyl-r(2), *c*(6)-bis(2'-furyl)piperidin-4-one oxime **(2)**, *N*-propanoyl-*t*(3)-methyl-r(2),*c*(6)-bis(2'-furyl)piperidin-4-one oxime **(3)**, *N*-benzoyl-*t*(3)-methyl-r(2),*c*(6)-bis(2'-furyl)piperidin-4-one oxime **(4)** are synthesized, characterized by melting point, one dimensional NMR (^{1}H & ^{13}C) and two dimensional ^{1}H-^{1}H COSY spectrum. The spectra shows that very broad signals at room temperature, but well resolved signals obtained at lower temperatures(+15, 0, -15, -30ºC). The spectra reveal the presence of two isomeric forms i.e., E and Z isomers for **1-4** at lower temperatures**.** The possible conformations for **1-4** (E and Z isomers) exist as an equilibrium mixture of alternate chair form **CA** and boat form $\mathbf{B_1}$ based on chemical shift, coupling constant values and torsional angle values.

Keywords **:** NMR Spectra, molecular conformation, N-acyl-piperdin-4-one oximes

Catalyst- and Additive-Free Cascade Reaction to Construct Benzo-Oxazine, Benzo-Oxazepine and Benzo-Oxazocine: O-Atom Transfer and New C=O, C-N and C-O Bond Formation

Arnab Ghosh,and Ramesh B. Dateer*
Centre for Nano and Material Sciences (CNMS), JAIN (Deemed-to-be University), Jain Global Campus, Bangalore-562112, India
arnabghoshanu1993@gmail.com, d.ramesh@jainuniversity.ac.in .

Heterocycles are an extremely important class of compounds, making up more than half of all known organic compounds[1]. Therefore, substantial attention has been paid to develop efficient new methods to synthesize heterocycles.

Here, we have done the exclusive synthesis of benzo-oxazine, benzo-oxazepine and benzo-oxazocine from arylpropioladehyde and hydroxyamino phenyl alcohol under the transition metal-free condition[2]. The O-atom transfer and formation of new C=O, C-N and C-O bond occurs at room temperature under one-pot reaction condition without using external oxidant and base[3]. The wide range of substrates are utilized for the synthesis of medicinally valuable and synthetically important N, O-containing six, seven and eight membered heterocycles in good to excellent yield. The UV-visible absorption study and photoluminescence studies have been showcased for functionalized heterocycles and their photo physical properties have been successively studied. Additionally, the proposed mechanistic elucidation is well supported by control experiment, and literature precedents.

Structural Investigation of Binding Mode of Vinblastine and Components with Normal and Modified DNA duplexes

Shweta Singh, Kumud Pandav and Prateek Pandya*
Amity Institute of Forensic Sciences, Amity University Uttar Pradesh, Noida,
Department of Biotechnology, Indian Institute of Technology Roorkee
ppandya@amity.edu

Vinblastine is known to be an indole alkaloid which is formed by the combination of vindoline and catharanthine. It is isolated from the plant *Vinca rosea Linn* and is used as a chemotherapeutic drug which acts as a part of chemotherapy regimen in various types of cancer treatment. The main function of vinblastine is that it alters the growth of fast growing cells in DNA and prevents them from growing (Pandya et al., 2014). Although vinblastine functions primarily by interacting with tubulin protein, it is also known to bind with duplex DNA. However, its mode of binding is considered to be major groove (Pandya et al., 2012). In this paper we have attempted to identify the binding mode by computational investigations using two types of DNA duplexes. We have also compared the binding interactions of structural halves of vinblastine viz., vindoline and catharanthine for their DNA binding ability. The study has revealed that vinblastine binds in the major groove of both normal and methylated DNA. On comparing their binding energy, it is revealed that the binding energy of vinblastine with normal and methylated DNA is ΔG = -6.58 and -6.98 respectively. Vindoline binds in the major groove of both normal and methylated DNA with the binding energy of ΔG = -6.44 and -6.26 respectively. On the other hand, Catharanthine binds in the minor groove of both normal and methylated DNA with the weaker binding interactions as indicated with ΔG = -5.92 and -5.77 respectively. The structural details of binding of Vinblastine, Vindoline and Catharanthine have also been disclosed which includes multiple hydrogen bonds, van-der-Waals interactions, etc.

Keywords – DNA interaction, Drug - DNA binding, Vinblastine, Molecular docking.

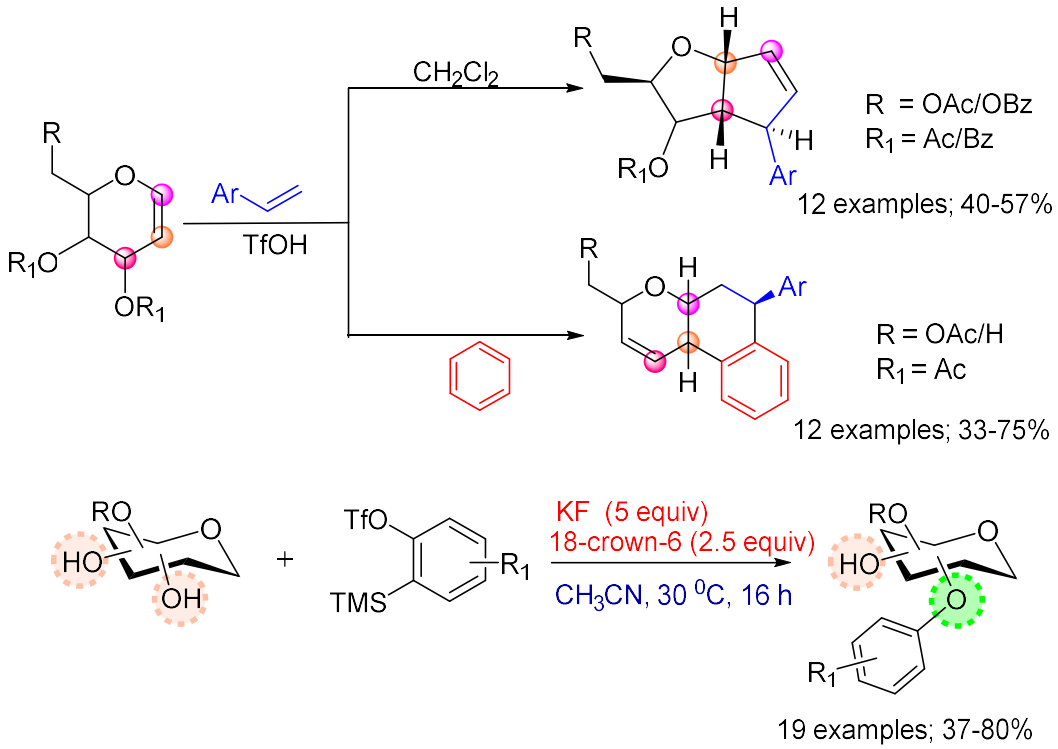
Development of Novel *C* and *O* – Glycosylation Methods for The Synthesis of Oxabicyclic Scaffold and *O*-Aryl Ethers

Monika Bhardwaj and Debaraj Mukherjee*
Indian Institute of Integrative Medicine (IIIM), Jammu 180001, India
monikabharadwaj103@gmail.com



Domino reaction has become one of the most effective methodologyfor the construction of various functionalized molecules and complex products. We have developed an unprecedented reaction strategy for the synthesis of complex oxabicyclic scaffolds with the reaction of glycals and stryrenes. The solvent played a major role in the outcome of the reaction. In the presence of participating solvents like benzene/toluene, cascade Ferrier C-glycosylation and double Friedel−Crafts reaction leads to densely chiral benzo-fused oxadecalins, whereas in DCM, an unprecedented ring-opening, ring-closing sequence generated cis-cyclopentanofurans. We carried out Isotope-labeling studies which revealed that glycosylation is the slowest step. We have also developed a new methodology for the *O*-arylation of carbohydrates under metal free conditions. Our approach worked well with mono, di and trihydroxy compounds and selectively arylated one hydroxyl in the presence of other.

Synthesis of biodegradable hydrogels PAAc by Inverse suspension polymerization

Sariqa Hayat[1]*, Arpit Sand[1],
[1*]Department of Chemistry, ManavRachna University, Faridabad, 121001, India
shariqahyatt05@gmail.com

Crosslinked Poly (Acrylic acid) was synthesized by inverse suspension polymerization. This process was investigated to determine the influence of different parameters like initiators concentration, stirring speed, and cross linker. An aqueous phase containing partially neutralized acrylic acid, crosslinking agent, and initiator agent was dispersed in an organic phase and stabilized by a surfactant. The polymerization was initiated by potassium persulfate ($K_2S_2O_8$) with MBA as a cross linker and SPAN 80 as a surfactant. The inverse suspension was carried out in toluene (hydrocarbon) as an organic phase because the availability of cross-linker in the aqueous phase is controlled by the partition coefficient of the cross-linker between the aqueous phase and the continuous hydrocarbon phase with varying conditions, such as initiator, cross- linker concentration, dispersant concentration degree of neutralization and stirring speeds on absorption capacities and effect of poly vinyl alcohol in both phases was investigated. The hydrogels were evaluated for their free absorption capacities in saline (0.9% NaCl). These results led to optimization of swelling and absorption behaviors.

Key words: Inverse suspension polymerization, Acrylic Acid, Hydrogels, Absorbency

Palladium-Catalyzed One-Pot Synthesis of 2-(Pyridin-4-yl)quinolines via an Unprecedented Multicomponent Reaction of Pyridine-4-carbaldehyde, 2-Iodoaniline and Triethylamine

Dr Atiur Ahmed
Memari College
atiur.chem@gmail.com

Quinoline is one of the most prominent N-containing heterocyclic aromatic compounds. Quinoline derivatives exhibit a broad range of biological activities like anti-bacterial, antifungal and HIV-1 replication inhibitors. In addition, they also provide other properties, such as anti-asthmatic, anti-hypertensive, anti-inflammatory and anti-platelet activities. In this regard, the literature on the advancement of alternative strategies for the formation of quinoline scaffold has experienced an extensive growth. The advantages of MCRs had drawn our attention to synthesize this scaffold. The reaction of pyridine-4-carbaldehyde and 2-iodoaniline in DMF (5 mL) in the presence of Et_3N (7 equiv.), $Pd_2(dba)_3$ (5 mol%) and PPh_3 (10 mol%) for about 24 h at 110 ^oC showed unprecedented result with the production of 2-(pyridin-4-yl)quinoline. The scope of this unprecedented reaction was explored with the preparation of variety of 2-(pyridin-4-yl)quinolines in one-pot by serendipity via the multicomponent reaction of pyridine-4-carbaldehyde, 2-iodoaniline and triethylamine. In this reaction, three new bonds were formed with the assembly of [3 + 2 + 1] atom fragments. The reactions deal with longer reaction time. However, the simultaneous formation of one C-N and two C-C bonds along with the unprecedented double C-H insertions of Et_3N have made this protocol novel.

Rapid synthesis of silver nanoparticles using aqueous plant extract

Anu Bala[1]
[1]. Department of Chemistry, CDLU Sirsa, Haryana-125055
ccihag@gmail.com

Currently, society is facing a crucial issue of environmental pollution. This results in the requirement of the development of a green method nanoparticle synthesis that is eco-friendly. This paper reports a non-toxic, cost-effective, facile, and rapid synthesis of silver nanoparticles using Delonix regia extract. The plant extract is used as a reducing and capping agent for the synthesis of silver nanoparticles. The change in color of the reaction mixture to brownish-yellow indicated the formation of silver nanoparticles. The nanoparticles were characterized by UV- Visible spectroscopy, FTIR, SEM equipped with EDS. The nanoparticles were found to be spherical.

OP-29

Unified Catalytic Enantioselective Total Synthesis of Sesquiterpenoids

Kundan Shaw, Vishnumaya Bisai*
Dept. of Chemistry, IISER Bhopal, Bhauri, Bhopal 462 066, MP
kundan17@iiserb.ac.in

Naturally occurring secondary metabolites cuparenes (1a-b, Figures1), herbertenes (3a-b) and ar-tenuifolene (6a-b) are sesquiterpenoids with cyclopentanoid and cyclohexanoid backbone. They possess a vicinal all carbon quaternary centers including at least one stereogenic quaternary center situated the psedobenzylic position. This sesquiterpenoids are isolated in 1964. Reportedly, these compounds are used to treat fungal infection, cancer, coughs, and arthritic pains. A general catalytic asymmetric route to either enantiomers of sesquiterpenes, cuparenes and herbertenes is disclosed from commercially available 3-methyl cyclopenten-2-one. Following a catalytic enantioselective addition of arylboronic acids to enone, compounds 7a-b with all carbon quaternary stereocenters are synthesized in up to 90% ee in the presence of Pd(II)-PyOx (pyridine oxazoline).

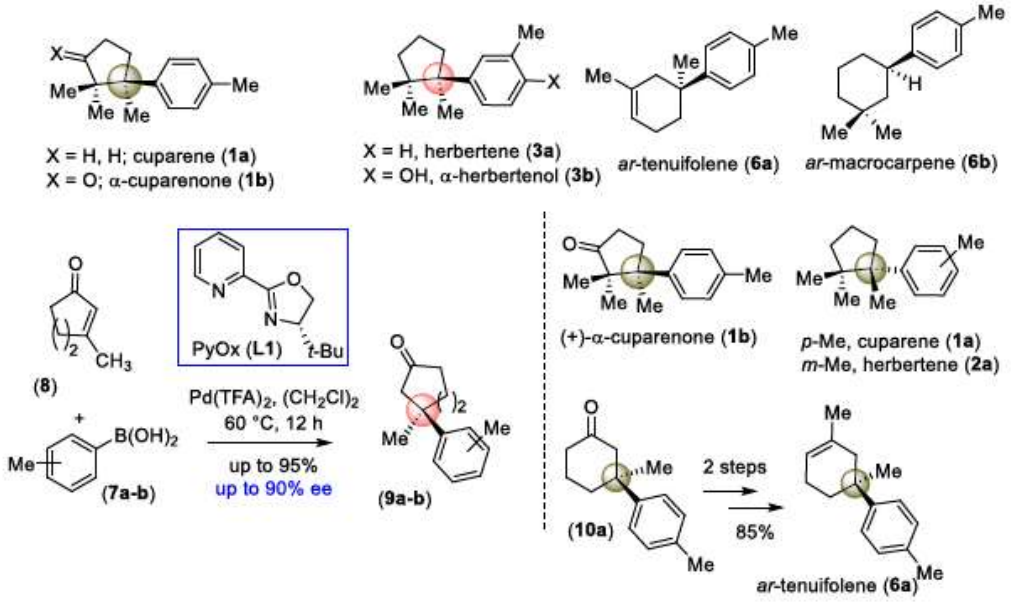

Figure:1 Naturally occurring sesquiterpenoids and our approach

The asymmetric total syntheses of (+)-cuparene (1a) (35% overall yield in 3 steps), (+)-herbertene (3a) (34% overall yield in 3 steps). First catalytic asymmetric total synthesis of aromatic sesquiterpene, ( )-*ar*-teunifolene (6a) is featured (3 steps, 75% overall yields) from commercially available 3-methyl cyclohex-2-enone 4. The enantioenriched 3,3-disubstituted cyclohexanone 12 is obtained from Pd(II)-catalyzed enantioselective (*p*-tolyl)boronic acid addition to 3-methyl cyclohex-2-enone in 95% ee, which is found to be the key intermediate. A diastereoselective methyllithium addition of this enantioenriched product followed by dehydration completes straightforward access to ( )-*ar*- teunifolene (6a).

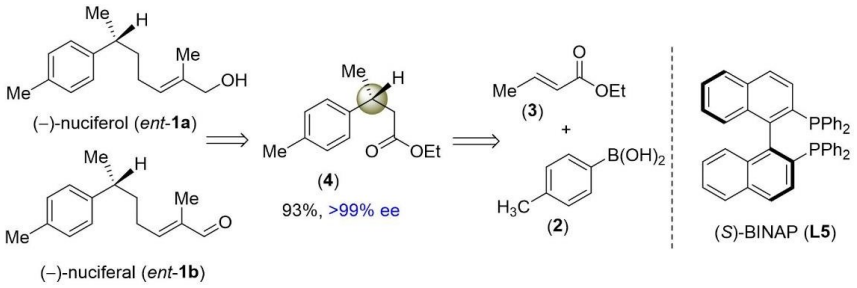
OP-30

Concise Asymmetric Total Syntheses of (-)-Nuciferol, (-)-Nuciferal, and (-)- Dihydrocurcumene via Rh(I)-Catalyzed Boronic Acid Addition

Mr. Souvik Pal
PhD Scholar, IISER Bhopal, India
souvikp@iiserb.ac.in

Among various sesquiterpenoids, naturally occurring aromatic bisabolanes are components of many plant essential oils that possess a benzylic stereogenic centers.[1] In particular, oxidized aromatic bisabolanes are attracting increasing attention because of their valuable biological activities.[2] The monocyclic aromatic bisabolane type sesquiterpene (+)-nuciferal (**1b)** was isolated from the wood oil of *Torreya nucifera* by Sakai, Nishimura and Hirose in 1965.[3] Although, there are many reports on racemic approaches to these congeners,[4] however, a catalytic asymmetric approach would be very much welcome to these targets having oxidized side chains, given their interesting biological profiles.



Scheme: Total Syntheses of (-)-Nuciferol and (-)-Nuciferal via Rh(I)-Catalyzed Boronic Acid Addition

In this synthesis we have shown a general catalytic asymmetric total synthesis of aromatic bisabolane sesquiterpenes, (-)-nuciferol (*ent*-**1a**), and (--nuciferal (*ent*-**1b**) in 5-6 steps in high chemical yields from commercially available (*E*)-ethylcrotonate.[5] A key catalytic enantioselective boronic acid addition onto (*E*)-crotonate in the presence of Rh(I)-(*S*)-BINAP (**L5**) afforded enantioenriched product with benzylic stereogenic center in 93% yield with up to >99% ee. Further exploration of aldehyde enabled the total synthesis of (-)-dihydrocurcumene (*ent*-**1c**).

Efficient Rh-Catalyzed Tandem C-C/C-N Bond Formation of Quinoxalines with Alkynes: Synthesis of Heterocyclic Quaternary Ammonium Salts

Kangkan Talukdar
Department of Chemistry, Indian Institute of Technology, Guwahati, Guwahati 781039, India.
iamkangkan@iitg.ac.in

An efficient Rh-catalyzed oxidative C-H activation/annulation of 2-arylquinoxalines with internal alkynes has been described using $Cu(OAc)_2 \cdot H_2O$ and $AgBF_4$ towards the syntheses of diversely substituted quarternary ammonium salts at room temperature. The mechanism of the protocol has been established on the basis of isolation of the 5-membered rhodacycle intermediate and kinetic isotope studies. Mild reaction condition, broad substrates scope and functional group diversity are the salient practical features.

Some oxazole containing sulfonamide analogs have been synthesized by reaction of 4-(2-{[(3-ethyl-4-methyl-2-oxo-2,5-dihydro-1H-pyrrol-1-yl) carbonyl] amino} ethyl) benzenesulfonyl chloride with 3-aminoacetophenone in acetone for 36 h. Which afforded N-(2-{4-[(3-acetylanilino) sulfonyl] phenyl}ethyl)-3-ethyl-4-methyl-2-oxo-2,5-dihydro-1H-pyrrole-1-carboxamide. Different anilines were treated with hydrochloric acid giving aniline hydrochloride, which on further reaction with urea resulted in various phenyl ureas. (N-(2-{4-[(3-acetylanilino) sulfonyl]phenyl}ethyl)-3-ethyl-4-methyl-2-oxo-2,5-dihydro-1H-pyrrole-1-carboxamide) i.e.sulfonamide was reacted with different phenyl ureas in presence of iodine to form oxazoles, which were recrystallised from ethanol. As-synthesized oxazole derivatives were characterized by different techniques. The antimicrobial activity of as-synthesized compounds were tested against (gram-negative bacteria) *Escherichia coli*, and (gram-positive bacteria) *Staphylococcus aureus*.

A Literature Serve on Study, Use and Recent Development in Synthesis of Antimalarial Drug Hydroxychloroquine (HCQ) will be Presented in Poster Format

Dr Manisankar Sau
Bhatter College, Department of Chemistry, P.O. – Dantan, Dist. – West Midnapore, Pin. -721426, west Bengal "Affiliated to Vidyasagar University"
sau.manisankar@gmail.com

Hydroxychloroquine (1, HCQ) is an effective nonsteroidal drug with anti-inflammatory activity for the treatment of rheumatoid arthritis (RA) in patients with cardiovascular disease. HCQ (**1**) has been identified as an essential antimalarial medication for a basic healthcare system, but global access to HCQ (**1**) has been hindered by high manufacturing costs of the API. Thus, the development of cost effective synthetic strategies to increase the global access to this important global health drug is of great importance.

Addressing the Background Amplification in RCA: Investigation of the Role of Circular DNA preparation with Three Different Ligation Techniques

Vandana Kuttappan Nair, Chandrika Sharma, Mrittika Sengupta, Souradyuti Ghosh
Dept. of Chemistry, Bennett University, Uttar Pradesh, India, PIN- 201 310.
pa-vandana.k@bennett.edu.in

Nucleic acid amplification is a valuable technique in biology and medicine because of its ability to detect trace of target nucleotide sequence. There are different types of nucleic acid amplification techniques such as Polymerase Chain Reaction (PCR), RT PCR, Loop Mediated Isothermal Amplification (LAMP), Rolling Circle Amplification (RCA) etc. Because of its power, simplicity and versatility, RCA can be chosen as an efficient method to develop sensitive diagnostic methods for a variety of target nucleic acids. In RCA, a short DNA or RNA primer is amplified to form a long single stranded DNA or RNA using a circular DNA template and special DNA or RNA polymerases. However, non-specific amplification originating from the choice of ligation process and the subsequent exonuclease treatment is a well-documented problem for RCA-based assay. In this study, three types of ligation processes are investigated, namely, self-annealing ligation, splint-padlock ligation, and sticky end ligation for their role in non-specific amplification. Upon comparison, our investigation demonstrated that only self-annealing ligation followed by combined exonuclease I and III digestion generated circular DNA with a complete absence of non-specific amplification in RCA. The absence of non-specific amplification is possibly due to its independence from the interaction of two or more DNA fragments for circular DNA synthesis. A mechanistic model to rationalize our findings has been proposed. Given the increasing application of RCA as a bioanalytical technique, we anticipate that this work will help the development of non-specific amplification-free RCA-based bioanalytical methods.

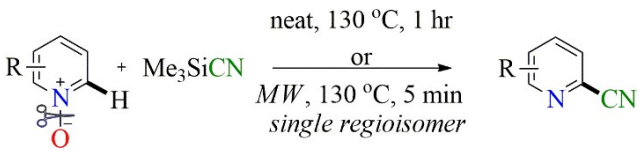
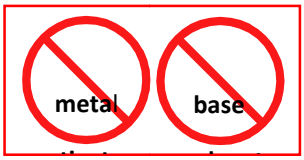
2-Cyanoheterocyclicscaffoldsareaprominentclassofsyntheticintermediates,which have found application in the preparation of a wide variety of biorelevant compounds and pharmaceuticals. To date, a number of synthetic protocol was developed with metal, base and activating agent. However, all of these bear their own limitations, such as (a) lack of regioselectivity (b) metal contamination; (c) required super-stoichiometric amount of base (d) toxic, hazardous, air and moisture sensitive reagent used as activator and (e) halogenated solvent used as solvent medium. Overall, these factors necessitate not only high cost but also exhibit environmental issues. Herein, we report a simple, one-pot, eco-friendly method for the C-H cyanation of heteroarenes *N*-oxides withtrimethylsilylcyanideundermetal-, activator-, base-andsolvent-free conditions.The present protocolis applicable to broad range of substrates with good chemoselectivity and regioselectivity. The synthetic utility of C2-substituted heteroaromatic nitriles is widely explored into several bio- active molecules including late-stage functionalization of anti-malarial drug quinine, and (±)-α- tocopherol modified quinoline derivative. Based on experimental studies, a plausible mechanism is put





forward involving dual role of trimethylsilylcyanideas cyanide source as well as activating agent. Finally, in terms of industrial perspective, this method is promising as it's simple, highly efficient, eco-friendly and easy toscale-up.

Scheme: C2-cyanation of N-heteroarene-1-oxides with trimethylsilyl cyanide

- ✓ Metal-, activator-, base- and solvent-free
- ✓ Excellent regio- andchemo-selectivity

Broad substrate scope,scale-up

- ✓ No aqueous work up, yields upto98

Interaction of Carbazole Derivatives with Xanthene Alkaloids: Spectroscopic Analysis and Density Functional Calculations

Dr. Nilanjan Dey[a] and Prof. Santanu Bhattacharya[a.b*]
[a]Department of Organic Chemistry, Indian Institute of Science, Bangalore 560012, India
[b]Director's Research Unit, Indian Association for the Cultivation of Science, Kolkata 700032, India
sb@iisc.ac.in, nilanjandey.iisc@gmail.com

Xanthene alkaloids, such as caffeine, theobromine, and theophylline have often been prescribed as psychoactive drugs despite their negative consequence in the human body. Here we have studied interaction of 9-ethyl-carbazole-3,6-dicarbaldehyde with different xanthene alkaloids using B3LYP/6-31G* level of theory.[1] The shorter π-stacking distance betweenprobe and caffeine as compared to theophylline and theobromine indicates preferential interactiontowards caffeine. Also, compound showed larger binding affinity towards caffeine (ΔE = 13.1 kcal/mol) than that of theophylline and theobromine. These observations could explain the experimentally-observed selectiveinteraction towards caffeine. The prescence of the low-lying LUMO orbitals indicates electron transfer from compound to caffeine in π-stacked complex. Such electron-transfer could explain the caffeine-induced fluorescence quenching. Further, to understand the electronic influence of substituents on analyte-binding, carbazole derivatives with different end-functional groups were included in studies. The π-stacking distances of caffeine complexes were found to be greatly affected by the electronics of the carbazole end-functionality. In the presence of electron-withdrawing substituent, two interactive moieties were found to be drifted apart, while for the electron-rich substituent, π-stacking distance becomes shorter. Experimentally also, we observed larger fluorescence quenching in the case of the electron-deficient substituent (-NO_2).

DFT Study of Metal-Free Organic Azides Addition to C-H Bond: Mechanism Part-II

Shougaijam Premila Devi, Rita Kakkar*
Computational Chemistry Laboratory, Department of Chemistry, University of Delhi, Delhi-110007, India
premila.devi.10@gmail.com, *rkakkar@chemistry.du.ac.in

Organic azides are important reagents for organic synthesis. Different types of reactions of azides with the C-H bond are possible, yielding useful products. The azide can decompose to nitrene before adding to the C-H bond or it can directly add to the C-H bond, forming the corresponding products. The DFT method B3LYP/6-311++G** was used to calculate the gas phase whole azide addition to C-H bond and substitution reaction of azides to alkane. Three organic azides **R**N_3 (**R** = Hydrogen (H), Methyl (Me), Acyl (Ac)) were reacted with alkane substrates, forming amine/amide and respective products. The direct addition of azide to alkane is exothermic and substitution reaction of azide is endothermic. The geometries of the transition states for various reaction steps studied here are described as “early” or “late” in good accordance with the Hammond postulate.

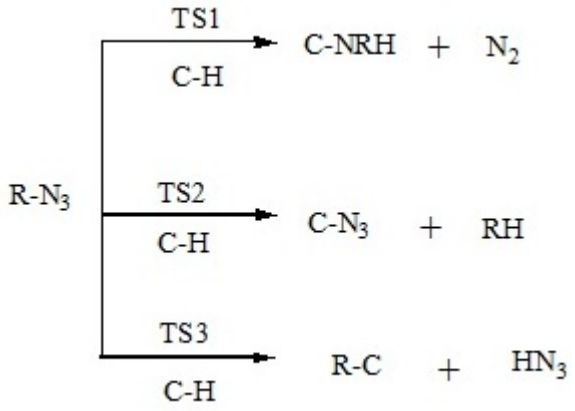

Figure: Three mechanisms of organic azide addition to C-H bond

Comparison of Surface Chemistry of Fluorosurfactants and Hydrocarbon Surfactants

Shruti Peshoria, Durgesh Nandini, R. K. Tanwar
Centre for Fire, Explosive and Environment Safety (CFEES), Defence Research and Development Organisation (DRDO), Timarpur, Delhi-110054, India
shruticfees@gmail.com

An alternative short-chain anionic fluorosurfactant (AFS) was synthesized to address the toxicity related issues of long-chain perfluorosurfactants including perfluorooctane sulfonate (PFOS) and perfluorooctanoic acid (PFOA). To make AFS more environment friendly than the legacy fluorosurfactants, recent strategies found in literature were incorporated into its structure. It consists of an alkene moiety, hetero atoms such as oxygen and sulfur and a shortened perfluorocarbon chain. Its structure analysis was carried out by ^{1}H NMR, ^{13}C NMR, ^{19}F NMR and FT-IR spectroscopy. The surface chemistry was examined by finding out its surface tension, dynamic surface tension (DST), critical micelle concentration (CMC) and contact angle. The surface tension was 17.6 mN/m at CMC (1.13 mmol/L). The DSTvalue above CMC for AFS was ~29 mN/m at ~10s for 2 mmol/L. It was compared with hydrocarbon surfactants such as sodium dodecyl sulfate (DST ~40 mN/m at ~10s for 10 mmol/L) and sodium lauryl ether sulfate (DST ~40 mN/m at ~10s for 10 mmol/L).It was found comparable to other commercial anionic fluorosurfactant (DST ~25-30 mN/m at 10s above CMC). The obtained surface tension values reflect its applicability in areas requiring high surface activity such as aqueous fire fighting foam (AFFF), paints, coatings and polishes.

Dissipative Self-Assembly For Accessing Functional Non-Equilibrium Gels

Subhajit Bal, Chandranath Ghosh, Krishnendu Das, Sahnawaz Ahmed, Tapan Ghosh, Ratheesh K. Vijayaraghavan, and Dibyendu Das*
Student, IISER Kolkata, India
sb17rs060@iiserkol.ac.in

Hydrophobic collapse responsible for the thermodynamically downhill aggregation of aberrant proteins, which has interestingly led to the development of a unique class of soft nanomaterials. However, hydrophobic collapse plays crucial roles in protein functions, from accessing the complex three-dimensional structures of native enzymes to the dynamic polymerizationof non-equilibrium microtubules. The non-equilibrium polymerization is accessed by the dissipative processes which are driven by the endergonic hydrolysis of chemical fuels such as nucleo side tri phosphates. Now, through the simple model systems, the transient self-assembled states are realized by utilizing the catalytic effect of histidine on the formation and breaking of ester bonds. First, histidine facilitates the ester bond formation, which then rapidly co-assembles to form a self-supporting gel. An out-of-equilibrium state is realized owing to the cooperative catalysis by the proximal histidines in the assembled state, driving the second pathway and resulting in disassembly to sol. Such non-equilibrium nanostructures were utilized to access temporal control over its electronic properties. Cooperative effects that use the dual role of imidazoles as nucleophile and as proton donor is utilized to achieve transient assemblies. This simple system mimics the structural journey seen in microtubule formation where the substrate GTP facilitates the non-covalent assembly and triggers a cooperative catalytic process, leading to substrate hydrolysis and subsequent disassembly.

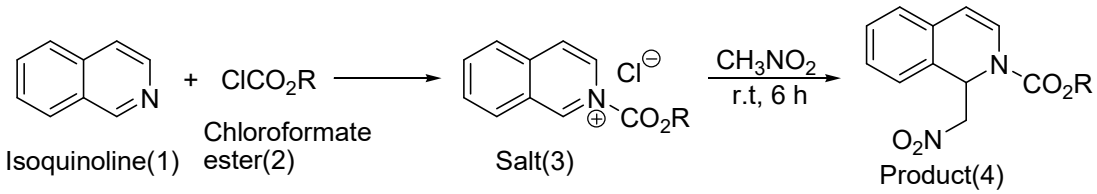
Coupling Reaction of Nitromethane with Aza-Aromatics Activated by Chloroformate Ester

Archana Pareek[1], Dr. Nagendra Nath Yadav*
Department of Chemistry, North Eastern Regional Institute of Science and Technology, Nirjuli, Arunachal Pradesh-791109
archanapareek610@gmail.com

Quinolines and isoquinolines, also known as aza-aromatics are structural isomer to each other. They are very important structural unit present in many natural products, pharmaceuticals and also in advanced organic materials used as electroluminescent dopants for light emitting devices.[1]

Herein, we report that when these aza-aromatics were activated with chloroformate ester activated compound(3) is formed, which when treated with nitromethane produces product(4) (Scheme 1).



Scheme 1

This method was used to couple nitromethane with various aza-aromatics to yield various dihydro isoquinolines/quinolines. The whole reaction proceeds in a single step, at room temperature and without any catalyst. The reaction is highly regio-specific making it a useful process for the synthesis of 1-substituted/2-substituted nitromethyl derivatives of dihydroisoquinolines/dihydroquinolines respectively in a single step.

Keywords: aza-aromatics, electroluminescent dopants, chloroformate ester, regio-specific.

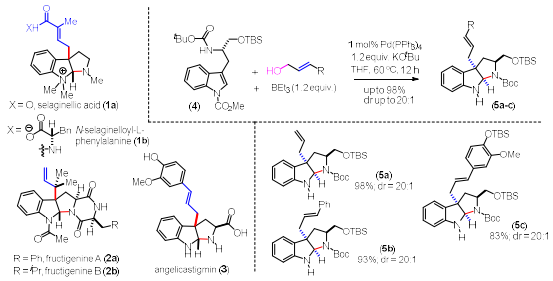
Catalytic N-Deacylative Alkylation of Indoles for The Total Synthesis of Hexahydropyrrolo[2,3-b]indole Alkaloids

Gavit Vipin Rajendra, Prof. Alakesh Bisai
Department of Chemistry, IISER Bhopal, Bhauri, Bhopal Bypass Road, Bhopal – 462 066, Madhya Pradesh
vipin16@iiserb.ac.in, alakesh@iiserkol.ac.in

Hexahydropyrrolo[2,3-b]indolines with a C(3)-quaternary center, have received significant attention both fromthe chemistry and biology communities because of their impressive pharmacological activities.[1]This structural motif is prevalent in myriad of architecturally complexand biologically active compounds which are mostly found in fungi, bryozoans, cyanobacteria[2] and other species. We targeted a subset of this class of natural products with hexahydropyrrolo[2,3-b]indole moieties having 1-(3,3-dimethylallyl) substituent flanked at the indolineC3 quaternary center (see, 1a-b.3)



Scheme: Hexahydropyrrolo[2,3-b]indoles alkaloids and our hypothesis via catalytic DaA.

In this direction, we have developed a catalytic synthesis of hexahydropyrrolo[2,3-b]indoles having C3 quaternary center from N-acyl 3-substituted indolesinvolving a key Pd(0)-catalyzed N-deacylative C-alkylations).[4] Eventually, a highly diastereoselective synthesis of chiral pyrroloindolines 5a-c is also shown from compound 4prepared from L-tryptophan. Given their biological importance and recent interest in the synthesis of complex pyrroloindoline alkaloids, this transformation is particularly notable in context of potentially interesting molecules.[5]

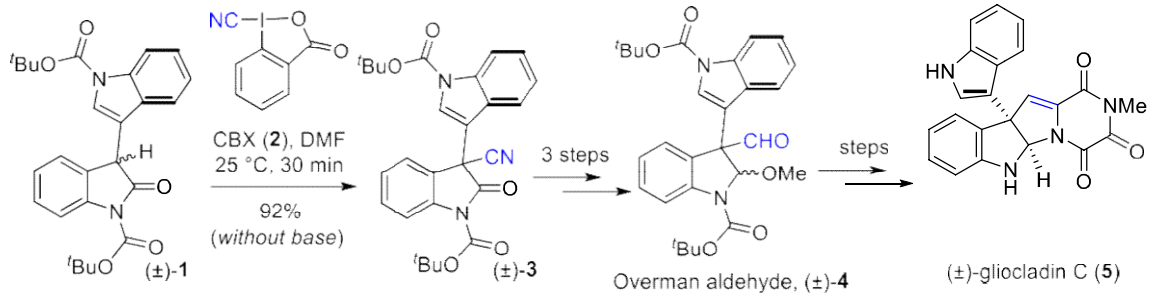
Oxidative Cyanation onto 2-Oxindoles: Formal Total Synthesis of (±)- Gliocladin C''

Arindam Maity
Ph.D Research Scholar, IISER Bhopal, India
arindam16@iiserb.ac.in

The tryptophan derived hexahydropyrrolo[2,3-*b*]indole diketopiperazine (DKP) substructure (**5**) is found in a large number of structurally diverse natural products.[1a] Compounds of this family that bear an indole moiety at the C-3 position have shown a considerable attraction due to their complex molecular structures and their potential biological activity as antiviral, and antibacterial agents. For example, (+)-gliocladin C (**5**), isolated in 2004 by Usami and co-workers,[1b] exhibits potent cytotoxic effects in P388 lymphocytic leukemia cells in vitro with a reported EC_{50} value of 2.4 μg/mL.[1b]

In this direction, we have developed a novel entry for the direct incorporation of a nitrile functionality onto 3-substituted 2-oxindoles [(±)-**3**] employing Cyano-1,2-BenziodoXol-3(1H)-one (CBX, **2**) reagents under *transition-metal free* oxidative condition.[2] This method affords a wide variety of 2- oxindole 3-cyano-3'-alkyl/indolyl [(±)-**3**] under *transition-metal free* condition (Scheme 1). It has been found that, the C-3 proton of 3-substituted 2-oxindoles which seems to be more acidic, are excellent substrates, where electrophilic cyanation works without the use of any base (Scheme 1).



Scheme 1: Formal Total Synthesis of (±)-gliocladin C (**5**).

Compound [(±)-**3**] having an all-carbon quaternary steroecenter synthesized *via* the key oxidative cyanation reaction of oxindole [(±)-**1**] using CBX (**2**) reagent under the standard condition (Scheme 2). Later, a formal total synthesis of (±)-gliocladin C [(±)-**4**] had been reported from aldehyde compound (±)-**4** [(±)-**4** known as Overman aldehyde] *via* few synthetic elaborations.[3]

Total Syntheses of Naturally Ocurring Bis-Hexahydropyrrolo[2,3-*b*]indole Alkaloids

Saina Shaheeda M K,[a] Arindam Khatua,[a] Alakesh Bisai*[a,b]
[a]Dept. of Chemistry, IISER Bhopal, Bhauri, Bhopal 462 066, MP
[a]Dept. of Chemical Sciences, IISER Kolkata, Kalyani 741 246, Nadia, WB E-mail: sainas@iiserb.ac.in; alakesh@iiserkol.ac.in

Total synthesis of naturally ocurring alkaloids can play a crucial role in bioactivity evaluation by providing access to significant quantity.[1, 2] It also provides platform for the innovation of new strategies for chemical synthesis. Further, catalytic asymmetric construction of organic molecules sharing all-carbon quaternary stereocenter is one of the challenging aspects of synthetic organic chemistry.[2] Enantioselective syntheses of targets having contiguous all-carbon quaternary stereocenters (see, **1-3**) invariably face even more difficulty.[3] Towards this, naturally occurring Bis- hexahydropyrrolo[2,3-*b*]indole alkaloids (**Figure 1**) with impressive diversity of biological activities drew our interest. Biosynthetically, they are imagined to be arisen from L-tryptophan.[3] Interestingly, a variety of alkaloids of this family show antibacterial and cytotoxic activities. Our catalytic asymmetric approach via the development of allylation at the pseudobenzylic position of 2-oxindoles (Scheme 1) will be discussed for the total syntheses of these alkaloids.[4]

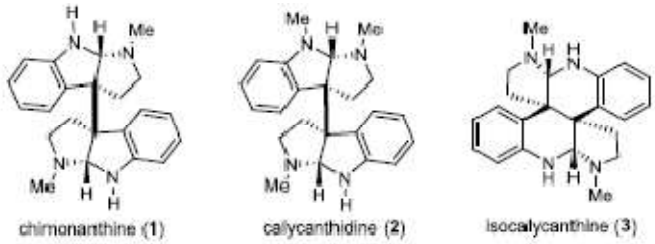

Figure 1: Bis-hexahydropyrrolo[2,3-*b*]indole alkaloids.

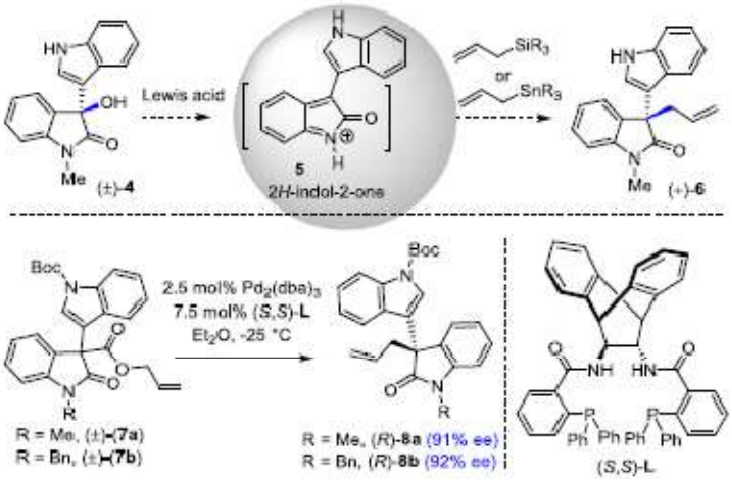

Scheme 1: Our approach to Bis-hexahydropyrrolo[2,3-*b*]indole alkaloids (**1-2**).

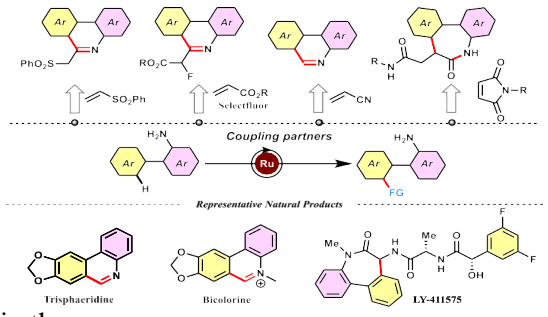
Harnessing Free Amine Directing Group in Ruthenium-Catalyzed C-H Bond Activation/Annulation Reaction for Natural Product Scaffolds

Deepan Chowdhury and Dr. Mahiuddin Baidya*
Department of Chemistry, IIT Madras
mbaidya@iitm.ac.in

Over the last two decades, transition-metal-catalyzed C–H bond activation/functionalization has emerged as a vibrant area of research, allowing functionalization of otherwise unactivated C–H bonds and offering unconventional disconnection approach for the synthesis of complex molecules.[1] Directing group (DG) plays pivotal role in this strategy in controlling reactivity and regioselectity issue. Obviously, consideration of free amine functionality as a DG is highly rewarding as it is an important constituent of a large variety of natural products and can also be easily transformed into variety of other functionalities.[2] However, materialization of this concept constitutes several challenges, like formation of stable yet unreactive transition metal complexes, direct nucleophilic reactions with coupling partners, as well as competing undesired side reactions such as oxidative degradation and *β*-hydride elimination. With judicious tuning of reaction conditions, we have successfully engaged free amine functionality as a DG in arene C-H bond activation reactions under inexpensive ruthenium catalysis. A cross-ring (5+1) annulation reaction between 2-arylanilines and activated olefins has been established for the synthesis of phenanthridines frameworks.[3a] Following this strategy, bioactive natural products such as *trisphaeridine* and *bicolorine* were also prepared in high yields. When maleimides was employed as coupling partners with ruthenium(II) catalyst, dibenzo[*b,d*]azepinones, which represent the core of several bioactive molecules including LY-411575, were isolated in very high yields.[3b] Dibenzo[*b,d*]azepinones with side-chains derived from chiral amino acids were also obtained in one step, highlighting the synthetic utility of this protocol. Mechanistic investigation covering deuterium exchange studies and *KIE* experiments suggest that the C□H bond activation takes place via an organometallic pathway in these processes.



Scheme 1: Ruthenium-catalyzed free amine directed cross-ring annulation.

DNA-binding and Photocleavage studies of Benzimidazo[2,1-a] ellipticine derivatives

Hanchate Pallavi
Pingle Government College for Women, Hanmkonda, 506001
hanchatepallavi@gmail.com

The DNA-binding properties of novel three Benzimidazo [2,1-a]ellipticine derivatives with CT-DNA has been investigated by absorption spectroscopy, EB-DNA displacement, circular dichroism, viscosity measurement and thermal denaturation studies. The experimental evidences indicated that these compounds could interact with CT-DNA through intercalation into the base pairs of DNA.The binding affinity of the compounds was quantified by calculating the K_b values, suggesting that compounds showing greater DNA binding propensity. Furthermore, to understand the binding mechanisms of these compounds with DNA, the effect of ionic strength on the fluorescence property of the system have been investigated. The results indicated the presence of electrostatic interaction via phosphate backbone of DNA helix. These compounds have also been found to promote the cleavage of plasmid pBR322 DNA under physiological conditions. The results indicate that DNA might also serve as the primary target of these compounds, hence demonstrating promise in their further development as potential anti-cancer agents.

Determination of Carbofuran in Various Samples of Water and Vegetables Using 3, 4-Dimethyl Aniline

Jaya Singh *[1], Pragya Awadhiya [2]
[1]Shri Shankaracharya Institute of Professional Management and Technology, Raipur, Chhattisgarh, 492015, India
[2]Rungta College of Engineering and Technology, Raipur, Chhattisgarh 492010, India
j.thakur@ssipmt.com, p_awadhiya@rediffmail.com

A carbamate insecticide carbofuran is determined by simple and sensitive spectrophotometric method. The method is based on the fact that on hydrolysis of carbofuran under alkaline condition carbofuranphenol is formed, on coupling it with 3, 4 dimethyl aniline. The colored dyes is formed which give absorption maxima at 455 nm. Beer's law is followed at the concentration range of 4 to 35 µg in a final solution of 25 ml. The molar absorptivity, sandell's sensitivity, standard deviation and relative standard deviation were calculated. The method was free from interference of other pesticides and diverse ions, and can be used for the determination of carbofuran in different water and vegetable samples.

Keywords- Carbofuran, spectrophotometer, 3, 4 -dimethyl analine, water and vegetable samples.

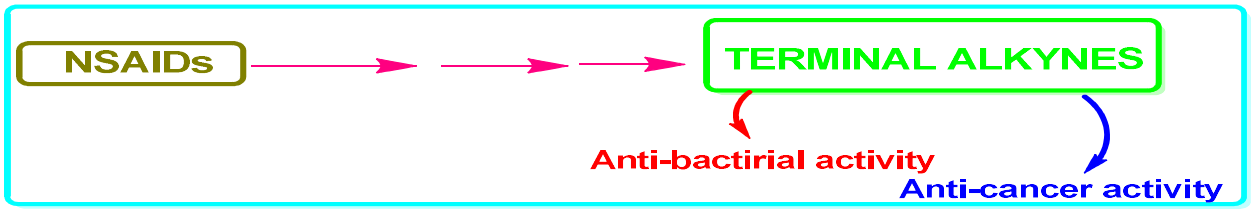
Synthesis and anti-bacterial and cytotoxic evaluation of terminal alkynes from NSAIDS via O,N,S Propargylation

P. Neeraja[a], K. Mukkanti[b], and S. Pal[c]
[a]Department of Chemistry, DVR College of Engineering & Technology, Kashipur(village),SangareddyDistrict, Telangana- 502285, [b]IST JNTUH, hyd-500085, [c]Department of Chemistry, MNR Degree & PG College, Kukatpally, Hyd-500085
pneeraja1986@gmail.com

A terminal alkyne is an alkyne in whose molecule there is at least one hydrogen atom bonded to a triply bonded carbon atom. According to Ferdinand Bohlmann, the first naturally occurring acetylenic compound, dehydromatricaria ester, was isolated from an *Artemisia* species in 1826. In the last two centuries over a thousand naturally occurring acetylenes have been discovered and reported. Polyynes, a subset of this class of natural products, have been isolated from a wide variety of plant species, cultures of higher fungi, bacteria, marine sponges, and corals.[1,2] Alkynes occur in some pharmaceuticals, including the contraceptive noretynodrel. A carbon–carbon triple bond is also present in marketed drugs such as the antiretroviral Efavirenzand the antifungal Terbinafine. The acidic hydrogen on terminal alkynes can be replaced by a variety of groups. Based on this we prepared some terminal alkynes from NSAIDS via N,O, Spropargylationin aqueous DMF media. All the synthesized compounds were purified by chromatographic techniques and well characterized by spectral data IR, NMR and Mass. These compounds were further used to test for antibacterial activity and anti-cancer activity.



Key words:Terminal Alkyne, NSAID, eco-friendly synthesis, Antibacterial activity and anti-cancer activity.

In search for new drug entities, the hybridization approach, is a promising route that can successfully target multifactorial diseases including cancer. Peptides are found throughout every cell and tissue in the body and are an integral part of most biologic processes. Clinically some of the peptides are used as antibiotics, anticancer drugs Triazoles are appeared as a suitable pharmacophoric equivalent as they are known for their versatile pharmacological applications. A new hybrid template designed by linking three pharmacophores, i.e. triazole, NSAID and peptide moieties have been used for the generation of a library of 20 molecules. All the products were characterized by IR, NMR and Mass spectral data. These compounds were further used to test for cytotoxic properties against Human Colon Cancer Cell Line A549, and antibacterial properties against both gm positive and gm negative bacteria.

Key words: Peptide, 1,2,3-Triazole, NSAID, Peptide Alkyne, eco-friendly synthesis, Anticancer activity and Antibacterial activity

A Cost Effective and Facile Method for the Synthesis of Graphene Oxide and its Microstructural Analysis

Jay Soni and Shikha Agarwal*
Synthetic Organic Chemistry Laboratory, Department of Chemistry, Mohanlal Sukhadia University, Udaipur, 313001
shikhaagarwal@mlsu.ac.in, jay.soni1993@gmail.com

A highly sustainable approach for the preparation of high-quality graphene oxide has been demonstrated by oxidation of graphite flakes via modified Hummers method using H_2SO_4 as an intercalating agent and $KMnO_4$ and H_2O_2 as oxidizing agents. The interpretation has been done under different reaction conditions. The present method does not require costly membranes for the separation of unwanted carbonaceous and metallic residues. The pre-cooling method is used to eradicate the explosive nature of intermediate steps. The synthesized graphene oxides are of high quality which was confirmed by a host of characterization techniques including FTIR, TGA, XRD, EDX, FE-SEM and AFM. The outcomes of characterization revealed that the synthesized product, GO-2 has high percentage of oxygen-containing groups and an increase in the carbon/oxygen (C/O) ratio established the synthesis of high-quality graphene oxide.

Keywords: Graphene oxide, Modified Hummer's method, Characterization

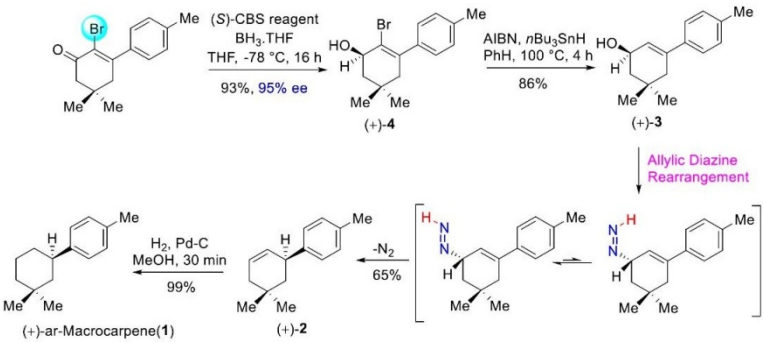
Total synthesis of (+)-*ar*-macrocarpene

Mr. Arindam Khatua
PhD Scholar, IISER Bhopal, India
arindam18@iiserb.ac.in

Sesquiterpenoids display diverse commercial applications in the pharmaceutical and perfumery industries together with their roles in interactions of plants with other organisms (e.g., allelochemicals and insecticides). Macrocarpenes including one such group of naturally occurring irregular sesquiterpenes possessing a 3,3,4′-trimethyl-1,1’-(bicyclohexyl) skeleton seems to be biogenetically derived from rearrangement of structural scaffold. These sesquiterpenoids were identified in foliage of Cupressus *macrocarpa* by Cool in 2005 in widely varying amount.[1] Since its isolation more than a decade ago, to date just a single racemic approach of *ar*-macrocarpene (**1**) has been featured in the literature by Srikrishna and co-workers in 2007.[2]

In this direction, we have developed the first catalytic asymmetric total synthesis of a sesquiterpene, (+)-*ar*-macrocarpene (**1**), in 7 steps with 42.1% overall yields from commercially available inexpensive 5,5-



Scheme: Total synthesis of (+)-*ar*-macrocarpene(**1**)

dimethylcyclohexane 1,3-dione.[3] This strategy relies on a key [3,3]- sigmatropic rearrangement effecting reductive transposition through allylic diazene rearrangement[4] (ADR) in a single step from intermediate allylic alcohol under the Mitsunobu reaction conditions with *o*-nitrobenzenesulfonyl hydrazide (*o*-NBSH). Enantioselective reduction of α-bromo vinylogous ester under the Corey–Bakshi–Shibata reduction[5] conditions forges the required stereocenter in the allylic alcohol (+)-**4** in a highly enantioenriched manner (95% ee).

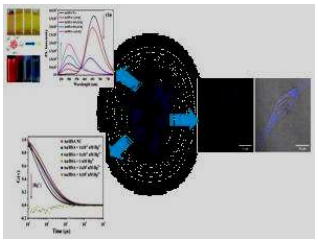
Owing to their unique quantized optical properties, low toxicity and bio-compatibility small sized luminescent noble metal nanoclusters (NCs) have been a topic of global contemporary research.[1-4]



In this work[#], gold nanoclusters (AuNCs) are synthesized within a protein template (Human Serum Albumin, HSA) which is exhibiting long excited state luminescence lifetime. These AuNCs own promising quantum yield about >10% having intense red luminescence with the peak centered at 660 nm and remarkable photo and cluster-core stability for a prolonged period (more than a year). This AuNCs were efficient to quantify the Hg(II) in solution as well as bound to the hormone, Insulin at single molecule sensitivity using fluorescence correlation spectroscopy (FCS) highlighting a sub-nanomolar detection limit. Cell-viability study directs that this NCs can be used as a probe for cell imaging by particularstaining of the cancerous cell, MDAMB231. Interestingly, this AuNCs is able to sense Hg(II) ion inside the MDAMB231 too. From the cell imaging study, it was revealed that the fluorescence of AuNCs was also quenched by Hg(II) ion inside the MDAMB231 cell lines. Thus the

output of our study apprises the sensitive *in vivo* as well as *in vitro* detection of Hg(II) ions using AuNCs as a probe.[#]

Deciphering the Evolution of Supramolecular Nanofibers through a Combined Microscopic and Spectroscopic Approach

Subhankar Kundu
Department of Chemistry, Indian Institute of Science Education and Research Bhopal, Bhauri, Bhopal, Madhya Pradesh, 462066, India
subhankar16@iiserb.ac.in

Supramolecular self-association of small π-conjugated organic molecules leads to well-defined nanoarchitectures like vesicles, micelles, low molecular weight gels, and other noncovalent aggregates with morphology-dependent tunable emission.[1-3] However, the correlation between the nature of the morphology (solid-state characterization) and the emission behaviour (dispersion-state analysis) of the aggregates are often rudimentary and can be benefitted through further analysis. In this present study, we demonstrated the detailed insight of the nanofiber evolution from a true solution.The field emission scanning electron microscopy (FESEM) imagesshowed the formation of the connected network of nanofibers for the dispersion having water content 80%. However, the formation of smaller-sized nanofibers in the dispersion was realized from fluorescence correlation spectroscopy (FCS) results (Fig. 1). Such smaller nanofibers can be transformed into the connected network of nanofibers through agglomeration during the solvent evaporation in the course of sample preparation for the electron microscopy. Further, the mechanism of nanofiber evolution was demonstrated through reversible morphological transformation in the presence of external stimuli (acid, base) and molecular modelling studies (Fig. 1). Hence, we believe the present study will provide a general experimental protocol to establish the relation between the nature of morphology and emission behaviour for all-organic fluorescent nanoaggregates.

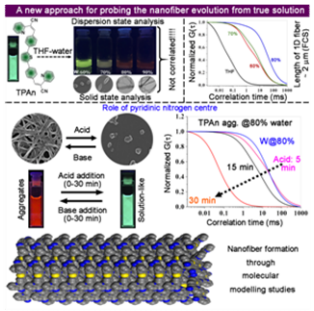

Fig. 1 Schematic illustration depicting the evolution of nanofibers from true solution through electron microscopy coupled with fluorescence correlation spectroscopy (FCS). The role of pyridinic nitrogen centre for the nanofiber formation was also demonstrated using FCS and molecular modelling studies.

In vitro distinctive complete inhibition of fibril formation of bovine and human serum albumins by methotrexate: A combined experimental and molecular simulation studies

Deb Kumar Khatua
Department of Chemistry, Indian Institute of Technology Kharagpur, Kharagpur-721302, India
debkumar.chem@gmail.com

Apparently never-ending lag-phase in the fibrillationof serum albumins (SAs) with low concentrated drug, methotrexate (MTX) is very promising and unique for clinical aspect toward inhibition of amyloidosis. Here we revealed that MTX significantly inhibits thermally induced bovine serum albumin and human serum albumin fibrillation by using fluorescence spectra, circular dichroism (CD) spectra, FESEM images, native gel electrophoresis and simultaneously theoretical studies. The kinetic profiles of BSA-MTX and HSA-MTX exhibit the appearance of lag phase followed by significant inhibition of fibrillation.Additionally, theobservation of negligible changesin CD dataof SA in presence of MTX at 65 ^{O}C, except a little increase of a-helix content, indicated that the secondary structure of SA is not significantly affected by thermal treatment. Furthermore, SEM studiesdistinct the formation of larger oligomeric speciesinstead of fibrillar aggregates during heating of SAsinpresence of MTX. Moreover, aggregation propensity, molecular docking and molecular dynamic simulation studies revealed a molecular level scenario that also explained high suppression of fibrillation and the longer lag-phase in kinetics by MTX, which further support experimental results. The results are beneficial for clinical potential having therapeutic relevance for drugs with structural similarity to MTX in controlling aggregation related diseases.

Organic and Inorganic Benzene Transform to Superalkalis: An *InSilico* Study

Swapan Sinha
School of Applied Sciences and Humanities, Haldia Institute of Technology, Haldia 721657,India. Email-swapansinha1995@gmail.com

Organic molecules, Benzene, and its inorganic version, Borazine are stable due to their aromaticity. The high ionization energies of these molecules suggest that they are reluctant to release the electron. Based on first principle calculation, we have shown the possibility of having superalkali molecules where benzene and borazine are acting as a core. Two different ligands, imidazole (IMD) and imidazole-based N-Heterocyclic carbene (NHC) have been used to get the superalkali molecules. It has been found that both benzene and borazine can from superalkali with these ligands and the ionization energy decreases to ~ 3.0 eV in tri-substituted complexes. We have observed that benzene can make better superalkali than borazine with suitable ligands like imidazole and NHC.

Cryostablization of the Cell Membrane of a Psychrotolerent Bacteria via Homeoviscous Adaptation

Shakkira Erimban, Snehasis Daschakraborty*
Department of Chemistry, Indian Institute of Technology Patna, Bihar 801106, India.
1821ch09@iitp.ac.in
*Corresponding Author: Dr.SnehasisDaschakraborty, snehasis@iitp.ac.in

Homeoviscous adaptation (maintenance of a critical balance between the saturated and unsaturated lipids) of the cell membrane of psychrotolerent bacteria is essential to protect them against freeze-thaw cycle. But, how does the homeoviscous adaptation protects the cell membrane during cold stress? In this letter, we answer this question using coarse grained (CG) molecular dynamics (MD) simulation technique. Based on the reported fatty acid profiles of a psychrotolerent bacteria at different temperatures, multiple lipid membranes are simulated at wide range of temperatures between 250 K and 300 K. We explicate how the homeoviscous adaptation minimizes the effect of cold stress on the structure and fluidity of the membrane. Partial freezing of the saturated lipid domain occurs with the self-aggregation of saturated and unsaturated lipids near melting temperature of the unadapted lipid membrane. The gel-like phase provides necessary local packing density to be sensed by the sensor proteins responsible for homeoviscous adaptation.

Atomic and Molecular Level Study of Substrate Binding and Small Ligand Migration in 8-Lipoxygenase

Vipin Kumar Mishra and Sabyashachi Mishra
Department of Chemistry, Indian Institute of Technology Kharagpur, India Email: iitkgpvipin@iitkgp.ac.in

Lipoxygenases are a family of non-haem, non-sulphur iron-containing lipid peroxidising enzymes that catalyse stereo and regio-specific formation of hydroperoxy derivatives from poly-unsaturated fatty acids in the presence of molecular oxygen[1,2]. Lipoxygenases are found in plants, animals and fungi. Their catalytic action has important consequences in a range of inflammatory and associated diseases. In this presentation, we would discuss the presence of a multi-channel network of oxygen migration pathways that allow an effective transfer of oxygen from bulk to the active site. We will discuss the relation between oxygen population in different migration channels and formation of different stereo and regio-specific products in wild-type as well as several mutants of lipoxygenases. The results indicate a possibility of evolutionarily optimized migration channels in lipoxygenases that allow accumulation of oxygen density at certain regions to attain regio-and stereo-specificity. In particular, we will highlight the effect of a single point mutation (L434F) on the conformational dynamics in the active site and consequent change in oxygen migration channels resulting in a complete change of the regio- and stereo-specificity of theproducts.

Role of Solvent in the Relaxation Dynamics of Core-Shell Au-SiO_2 Nanoparticles

Hemen Gogoi,[a] Bala Gopal Maddala,[b] Anindya Datta[*a]
[a] Department of Chemistry, Indian Institute of Technology Bombay
[b]IITB-Monash Research Academy
Mumbai, Maharashtra-400076
[*]E-mail: adutta@iitb.ac.in

Relaxation dynamics of surface plasmons in Au-SiO_2 core-shell nanoparticles has been followed by femtosecond pump-probe technique.[1,2] The effect of excitation pump energy and surrounding medium on the time constants associated has been elucidated. A gradual increase in the electron-phonon relaxation time with pump energy is observed and can be attributed to the higher perturbation of the electron distribution in AuNPs at higher pump energy.[3] Variation in time constants for electron-phonon relaxation in different solvents is rationalized on the basis of their thermal conductivities, which govern the rate of dissipation of heat of photoexcited nanoparticles.[4] On the other hand, phonon-phonon relaxation is found to be much less effective than electron-phonon relaxation and the time constants associated with it remain unaffected by thermal conductivity of the solvent.

Synthesis and characterization of cobalt nanoparticles to investigate their acoustical properties and biological potentials

Vijayta Gupta[a]*, Meena Sharma[a], Pawan K Verma[b], Vinay Kant[c] and Pawan Kumar[c]
[a] Department of Chemistry, University of Jammu, Jammu & Kashmir, India.
[b] Division of Pharmacology & Toxicology, SKUAST-Jammu. [c] Indian Veterinary Research Institute, Izatnagar, Bareilly, India. *E-mail: vijayta1gupta@gmail.com

In present research, cobalt (Co) nanoparticles were synthesized by metal reduction method followed by their characterization to study acoustical parameters and biological potentials. Five different concentrations (0.05-0.25% by weight) of Co nanofluids were developed by suspending Co nanoparticles in gum arabic – ethylene glycol (EG) mixture followed by ultrasonication. The variation of speed of sound, viscosity and density, and different acoustical parameters of these nanofluids were investigated at different temperatures. Co-EG nanofluids exhibits a maximum speed of sound for a specific concentration (0.15 wt %), which is higher than the speed of sound in the EG. Speed of sound was decreased with the rise of temperature. Viscosity and density of nanofluids increased with concentration and decreased with temperature. Variations in acoustical parameters were used to understand the associations between particle and fluid molecules. In wound healing study, Co nanoparticles ointment increased per cent wound contraction on day 5, 10 and 15 post-wounding in comparison to control group. Quality of healing was also better in wounds treated with Co nanoparticles. In conclusion, acoustical results are helpful in extending the use of Co-EG nanofluids to different industrial areas. Co nanoparticles might be envisioned as a promising wound healing agent.

Mechanism of Pb^{2+} sensing in water with PEI-capped photoluminescent CdS quantum dots

Sharmistha Das, Soumyadipta Rakshit,*Anindya Datta*
Department of Chemistry, IIT Bombay, Powai, Mumbai-400076
* adutta@iitb.ac.in (AD)

Polyethyleneimine (PEI) capped CdS quantum dots (QDs) have been synthesised directly in water and their metal-ion sensing properties are investigated. Photoluminescence (PL) of the QDs is severely quenched (~80%) in presence of lead ions along with decrease in PL lifetime. We further elaborate upon the mechanism of quenching using transient absorption (TA) measurements of CdS QDs in presence of various concentration of Pb^{2+} ions. We observe signatures of efficient hot electron transfer.[1] Mechanism of quenching is found to be surface adsorption of Pb^{2+} ions and quenching due to electron transfer. Surface adsorption binding constant is estimated to be 5.35×10^{4} M^{-1}.[2] Additionally electron transfer rate from conduction band edge is calculated to be 1.45×10^{11} s^{-1}.[3] Driving force, QD surface quality and capping agent are found to be deterministic factors in the observed response and selectivity to metal ions.

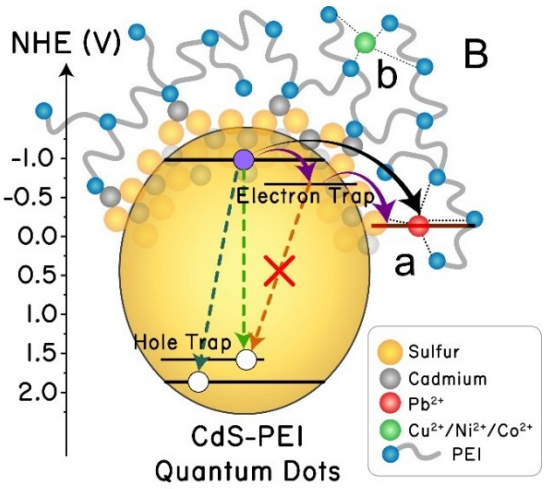

Figure 1. Schematic representation of PL quenching mechanism of CdS QDs in presence of lead ions.

Ultrafast carrier dynamics of Cu doped CdSe nanotetrapods

Fariyad Ali, Sucheta Banerjee,[a] Anindya Datta[b]
Department of chemistry, IIT Bombay, Powai, Mumbai, 400076
[a]Faculty of chemistry, SP college pune
[b]Faculty of chemistry, IIT Bombay, adutta@iitb.ac.in

It is important to know the carrier relaxation in excited state of Cu doped CdSe nanotetrapods (NTPs) as it has many applications in in different fields like LEDs, photovoltaic devices, solar cells and transisters etc.[1,2] We have studied the optical properties and exciton dynamics after Cu doping in CdSe TPs in excited state. The PLQYs of CdSe TPs increased from 1.7% to 38% after Cu doping and the PL decay time also increased because conduction band electron recombine to the Cu^{2+} (d-level) hole instead of direct electron-hole recombination.[3,4] We have performed Transient Absorption (TA) Spectroscopy to know the hot electron cooling time and recovery kinetics of exciton at different pump power in excited state. It is observed that the hot electron relaxation time increased from 400fs to 540fs and recovery kinetics also slowed after Cu doping in CdSe TPs. So slow electron cooling and recovery kinetics is depend on dopant concentration.[5]

Diffusion viscosity decoupling in supercool water and binary mixture: Explanation using the Translational Jump-diffusion Approach

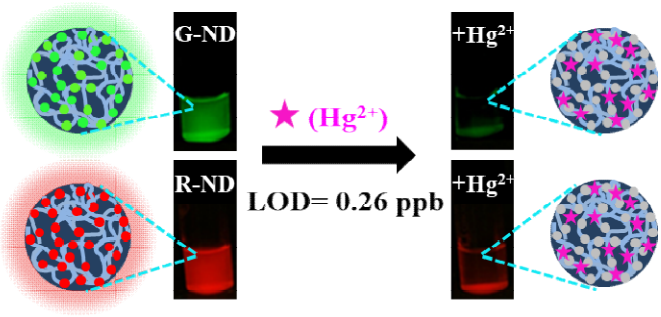
Vikas Dubey*, Snehasis Daschakraborty#
Department of Chemistry, Indian Institute of Technology Patna, Bihar 801106, India.
* vikas.pch17@iitp.ac.in,
# snehasis@iitp.ac.in

Water and its binary mixture are fascinating liquids withvarious anomalous properties. The decoupling of diffusion from the viscosity of the medium is one of them. This anomaly depends on several factors like temperature, pressure, solute size, neighboring particle, and the dynamical heterogeneity of liquid. The diffusion-viscosity decoupling can be easily understood from the violation of the Stokes-Einstein (SE) relation, which connects the diffusion of the molecules with the viscosity. The recent development in experimental techniques makes it possible to observe the above decoupling phenomena in great detail inthe supercool regime. Here, we usea molecular dynamics simulation tool to observe the breakdown in the pure water and water/methanol binary mixture in a wide range of temperature and pressure. We have used the translational jump-diffusion (TJD) approach to calculate the jump-diffusion coefficient D_Jump and explain the role of jump-diffusion in the SE breakdown. We have separated out the jump-diffusion from the total diffusion of the molecules and found that the residual part strongly couples to the viscosity and thereby follows the SE relation. This TJD approach, therefore, puts forward an alternative approachfor explaining the experimentally observed SE breakdown in supercooled water and related medium.

Quantum Dot-Based Hybrid Coacervate Nanodroplets for Ultrasensitive Detection of Hg^{2+}

Shivendra Singh
Indian Institute of Technology Indore
phd1901131015@iiti.ac.in

Multifunctional organic-inorganic hybrid materials with inherent optical, electrical and/or magnetic properties find tremendous importance in various fields such as sensing, therapeutics, bio-imaging, and light-emitting devices.[1-2] Herein, we have fabricated a simple organic-inorganic hybrid nanocomposite-based sensing platform for the detection and efficient removal of Hg^{2+} ions from contaminated water simultaneously. The self assembly of negatively charged CdTe quantum dots (QDs) in the presence of positively charged poly(diallyldimethylammonium chloride) (PDADMAC) leads to the formation of luminescent nanodroplets with average size of 430 ± 20 nm. Our findings reveal that Hg^{2+} ions specifically associate with the porous structure of these nanodroplets via electrostatic interactions with



the free carboxylate groups of MSA ligands at the surface of CdTe QDs and undergo photoinduced electron transfer (PET) with photoexcited QDs. The limit of detection (LOD) for Hg^{2+} sensing with our present system is estimated to be 1.32 nM which is significantly lower than most of the earlier reported self-assembled materials. Moreover, these hybrid nanodroplets efficiently sequester trace quantity of Hg^{2+} from contaminated water. The overall performance of our present system towards Hg^{2+} remediation is superior over most of the earlier reported hybrid nanocomposites in terms of fast uptake kinetics (within 15 min), ultrasensitive detection (LOD: 0.26 ppb), and high sequestration efficiency (98.3%). Our present findings in particular, the tailorability of surface ligands and inorganic nanoparticles in hybrid nanodroplets provide great advantage for the development of multifunctional nanomaterials for diverse range of applications.

Fabrication of Biocompatible pH-Responsive Luminescent CoacervateNanodroplets toward TheranosticApplications

Bhawna Saini, and Tushar Kanti Mukherjee*
Department of Chemistry, Indian Institute of Technology Indore, Indore 453552, M.P., India
phd1801131014@iiti.ac.in, tusharm@iiti.ac.in

Cytotoxicity is one of the essential in-vitro studies used forbioimaging applications. Herein, we have fabricateda pH-responsive inherently luminescent carbon dot (CD) – based coacervate nanodroplets (NDs) in the presence of cationic polymer PDADMAC. Thephysicochemical and photoluminescence properties have been explored as a function of equilibration time (1 and 18 h), pH (2-12), and ionic strength (1-1000 mM). Equilibrating the binary mixture of CD and PDADMAC for 1 and 18 h results in the formation of SNDs (73.0 ± 2.3 nm) and LNDs (□400 nm). While these NDs are stable in a broad pH range (5−12) and low ionic strength (<200 mM) medium, however they disassembled in lower acidic pH(<5.5)and a high ionic strength (>200mM) medium. These negatively charged (ζ-potential =−17.0±0.5mV) ND scans pontaneously sequester neutral, cationic, anionic dyes and anticancer drug doxorubicin inside their porous nanostructure without any structural disruption. Biocompatibility assay in BHK-21 reveals the non-toxic nature of these SNDs. Finally, the bare and ethidium bromide (EtBr)-loaded SNDs have been utilized toward time-dependent cellular uptake experiments. While released EtBr in the cytosol specifically bind with nucleic acid within the cell nucleus without losing their affinity, free CDs on the other hand stain the whole cell without any specificity.Takentogether, our present findingshighlight the potential of thesebiocompatible inherently luminescentpH-responsive NDs toward theranostic applications.

Peculiar photophysics of Schiff bases has drawn significant interest over the past few decades. Torsional motion coupled with rapid proton transfer have been predicted to be the major non radiative pathways contributing to the very low lifetime as well as emission intensity of these class of molecules.[1] In this work we have tried to hinder the rapid Excited State Intramolecular Proton Transfer (ESIPT) of HSALIMP by complexation with Zn^{2+} and Al^{3+}. As expected both the metal complexes now undergoes a slower single exponential decay as compared to the uncomplexed ligand, however the Zn complex decays faster than that of its Al congener.[2] This has been rationalized by considering the monomer dimer equilibrium of both the complexes. Inhibition of π-π stacking in Zn complexes by formation of bridge bonds and corresponding effects on dynamics has also been examined.[3] Effect of addition of one more Zn centre further delineates the complex interplay between structure i.e. π-π stacking interactions and electronic factors which might be operative in determining the lifetime and quantum yield of this series of complexes

Multi-Spectroscopic Monitoring of β-Cyclodextrin encapsulated Novel Anti-Alzheimer's Agents and Investigating their Response to Mitochondrial Respiration

Srishti Sharma[a] and Kallol K. Ghosh[a]*
[a]School of Studies in Chemistry, Pt. Ravishankar Shukla University, Raipur 492010 (C.G.)
srishtifromindia@gmail.com

The elusive and multifactorial nature of Alzheimer disease (AD) clearly shed light on the fact that currently available drugs and therapies are unanswerable to the treatment of AD. To meet this end, formulations which could enhance the efficacy of the drugs and their delivery to the targeted enzyme need to be developed for improving the cognition. Thus, in our work, host-guest complex between novel anti-AD agents (PC-25 and PC-37) and β-CD are prepared and tested for their stability at three different temperatures (293, 298, 305 K). The formation constant (K_a) advocated the successful complexation and Job's plot indicated their 1:1 stoichiometry. Moreover, thermodynamic parameters [Gibb's free energy (ΔG), enthalpy (ΔH) and entropy (ΔS)] have well supported over the spontaneity and nature of the inclusion complexes (ICs). The complexation behaviour are studied using FTIR and the extent of complexation are determined by NMR (1H NMR, COSY and NOESY) measurements. ICs induced alterations are examined in mitochondrial respiration for scrutinizing the efficacy of these β-CD encapsulated ICs. The ICs are tested for their potency and inhibitory effects on mitochondrial respiratory rate along with their respective IC50 values. This intriguing and promising approach is the subject to another perspective while the exploration may pave a way to impede this neurodegenration.

Studies of Host-Guest complexation between functionalized Ionic Liquids and Cyclodextrins

Subhashree Jayesh Pandya and Kallol K Ghosh*
School of Studies in Chemistry,
Pt. Ravishankar Shukla University, Raipur (C.G.) 492010, India.
subhashree210490@gmail.com

Host-guest complexation between oxime functionalized ionic liquids (ILs) (S)-2-((hydroxyimino)methyl)-1-(2-((1-(octylamino)-1-oxo-3-phenylpropan-2-yl)amino)-2-oxoethyl)pyridin-1-ium bromide (2-PyPheC8) and (S)-4-((hydroxyimino)methyl)-1-(2-((1-(octylamino)-1-oxo-3-phenylpropan-2-yl)amino)-2-oxoethyl)pyridin-1-ium bromide (4-PyPheC8) with cyclodextrins (α and β CDs) have been studied. The formation of inclusion complexes (ICs) were confirmed by UV–vis spectroscopy which further have been validated by FT-IR, ^{1}H NMR and COSY methods. The binding constant of ICs complex was determined by UV–vis spectroscopy and the effect of temperature was also checked. Job's plot method revealed formation of 1:1 stoichiometry. Significant thermodynamic parameters like enthalpy (ΔH), entropy (ΔS) and Gibb's free energy (ΔG) were also calculated. The FT-IR data provided the information of functional groups involved in complexation. The 1H NMR confirmed the H-bonding, electrostatic and hydrophobic interactions were involved in the formation of complexes. The study of supramolecular chemistry may help in developing the potential application in modern science and fundamental research.

manojbanjare7@gmail.com

The present study investigates the effects of deep eutectic solvents (DESs) on the micellization behaviour of long chain imidazolium based ionic liquid (IL) i.e., 1-decyl-3-methylimidazolium tetrafluoroborate [Dmim][BF_4] in aqueous media. The DESs synthesised is composed of 1 : 2 mole ratio of choline chloride and glycerol/urea and furthermore characterized by FTIR and ^{1}H-NMR spectroscopic techniques. The intermolecular interactions in IL with Gly/urea based DESs solutions are investigated by various techniques including the FTIR, ^{1}H-NMR, and 2D NOE spectroscopy. FTIR spectroscopy was used to study the [Dmim][BF_4]-DES interaction that leads to tune the micellar structure of the [Dmim][BF_4] within the Gly/Urea based DES solution. ^{1}H-NMR and 2D NOE spectroscopic methods are further employed to strengthen our claim on the feasible structural arrangements within the aqueous [Dmim][BF_4] -DES self-assembled structures. The present results are expected to be useful for colloidal aspects of DES and their mixtures with water. Key words: Ionic liquid, Deep eutectic solvent, Molecular interaction, Spectroscopy.

Palladium-Catalyzed Ortho-Benzoylation Of Sulfonamides Through C–H Activation: Expedient Synthesis of Cyclic N-Sulfonyl Ketimines

Subhadra Ojha and Niranjan Panda*
Department of Chemistry, National Institute of Technology Rourkela, Odisha-769008, India
subhadraojha359@gmail.com

Being a ubiquitous functional group in biologically active compounds, aryl sulfonamides possess a variety of pharmaceutical activities.[1] Sulfonamides also serve as a versatile synthon to access a myriad of S- and N-containing molecules.[2] Recently we have developed a Pd-catalyzed protocol for the ortho-carbonylation of sulfonylarenes by non-hazardous aryl aldehydes as a carbonyl precursor by revealing the directing potential of the sulfonamide group for C-H activation under ligand-free conditions.[3] Deuterium labeling experiment and KIE study suggested that the initial C- H activation step is an irreversible process and is also the rate determining step. The scope of this strategy has been extended to the one-pot two-step synthesis of cyclic N-sulfonyl ketimines. Mild reaction conditions and the simple experimental procedure for C- H activation make the process interesting and could be a preferred route to access cyclic N-sulfonyl ketimines over the reported multistep approaches involving the use of highly reactive organolithium or Grignard reagents.

A novel approach towards expanding the utility of Deep eutectic solvents as a biocompatible co-solvent for α-chymotrypsin

Niketa Yadav, Pannuru Venkatesu*
Assosicate professor, University of Delhi
e-mail: niketayadav2208@gmail.com, venkatesup@hotmail.com

Since the introduction of deep eutectic solvents (DESs), numerous reports have surfaced describing its tunable properties and environmentally benign nature. Due to such favorable properties of DESs, they have found a wide variety of applications. Moreover, in order to harness the potential of proteins in numerous industries, there is an emergent need to find a suitable cosolvent that is biocompatible with protein and is also environmentally safe. In this context, this work presents a systematic evaluation of effect of two deep eutectic solvents (DESs), namely, choline chloride-urea (ChCl-urea) and choline chloride-glycerol (ChCl-gly) on the structural and thermal stability along with activity of enzyme α-chymotrypsin (CT) using circular dichroism (CD), UV−visible, steady state, and thermal fluorescence spectroscopy. It was observed that the presence of DESs does lead to enhancement in the thermal stability of CT along with the preservation of activity. The enzymatic activity was well maintained in both the DESs, and the deleterious effect of urea was overcome by ChCl-urea on the enzyme. Thus, the negative outcome of urea was overpowered by the combination of ChCl and urea. Overall, both the DESs can be described as potential biocompatible, sustainable, and promising cosolvents for CT with enhanced structural and thermal stability along with preservation of its activity.

Nanostructures of Diphenylalanine-Nucleopeptide: Their morphological characterization and applications as new materials for biosensors

Dr. Om Shanker Tiwari
Post-Doctoral Scientist, Indian Institute of Technology, IIT Delhi, India
otiwari1992@gmail.com

The hierarchical architectures induced by self-assembly of peptides have paved a new path for novel applications in biomaterial and material sciences. Nanostructures originating from the supramolecular assembly of peptides have wide range of applications in tissue engineering, drug delivery and nanoelectronics.[1] The unique mode of peptide self-assembly is an ideal tool for effective bottom-up approach towards nanomaterial architecture.[2] The discretely well-organized structures of diphenylalanine observed single crystal X-ray diffraction[3] and their wide range of applications have inspired many scientific achievements in the field of biomaterial, bio-sensing and nanotechnology.[4]

From our laboratory, we have established hitherto unknown effects of additional stacking and H-bonding with C-terminal ligands such as purine and pyrimidine nucleosides on the morphological features of the Phe-Phe dipeptide.[5-7] The nanostructure of Phe-Phe based nucleopeptide produced a wide range of spherical nanoparticles which was utilized for encapsulation and external stimuli triggered release of small molecules carboxyfluorescein. It is therefore envisaged that simple hybrid peptides can be used as a scaffolds in biology, nanotechnology, and materials science which include viral capsids, certain enzymes, ion channels, and the pores of ultrafine separation systems.

Nanostructures have inherent properties to create the platform for nanotechnology and self- assembly of diphenylalanine (Phe-Phe) has been widely used at its mesoscopic to nano-metric level. Excellent stability and unique self-assembly of modified peptides under a wide range of conditions inspire to investigate their possible semiconducting behavior. Hydrophobic surface of Torey carbon electrode coated with nucleopeptides are expected to retain their self-assembly and consequently exhibit enhanced conductive nature depending on the substituents. Furthermore, Phe-Phe can be further modified attaching with disulfide bond containing lipoic acid to study their redox activity on gold electrode through self-assembled monolayer (SAM). Modified electrodes thus obtained, can effectively be used for selective detection of bio-analytes uric-/ascorbic acids, glucose and transition metal ions. These nanostructures generated from the modified Phe-Phe motifs will be utilized for various practical applications viz., bio-sensing, catalytic activity, semiconducting materials and as vehicle for hydrophobic drugs. Diphenylalanine and its derivatives attached with electronically rich ferrocene moiety would make conductor / better semiconductor which can be used to fabricate modified electrodes for water splitting.

Structural and Opto-electronic Study of 2D Black Phosphorus

Anirban Kundu
PhD, Institute of Nano Science and Technology, India
anirban.ph14217@inst.ac.in

In order to understand the structural stability of layered BP flake, High-Pressure Raman spectroscopy of a few-layer BP flake has been carried out. The extensive study of Raman spectra under applied pressure confirms the structural stability of BP flake for mechanically harsh conditions as high as ~ 5.9 GPa. At applied pressure of ~ 4.2 GPa, an orthorhombic to rhombohedral phase transition has been observed, which is simultaneously reversible and partial. The phase transition pressure has been identified experimentally from the abrupt change in blueshift to redshift of in-plane Raman vibrational modes (B2g and A2g). The experimental results confirm the coexistence of both the crystal phases (orthorhombic and rhombohedral) is possible over the transition pressure (> 4.2 GPa) and reveals the possibility of a metastable state.

Apart from mechanical stability, it is also necessary to understand the behavior of BP flake upon optical exposure to explore its possible opto-electronic applications. In order to understand the light to matter interaction, the effect of laser irradiation on BP flake has been investigated by acquiring the Raman spectra with the variation of laser power and laser energy. The variation in laser power produces a similar kind of shift in Raman vibrational modes, as observed in the conventional electrostatic field gating effect, which is as effective as conventional electrostatic gating effect.

Role of Metal Centres in the Catalytic Activity of DapE Enzyme from QM/MM Approach

Atanuka Paul and Sabyashachi Mishra
Department of Chemistry, Indian Institute of Kharagpur
mishra@chem.iitkgp.ernet.in

Due to the increase in the number of bacterial infections and bacterial resistance to antibiotics, novel drug discovery constitutes an important research effort [1]. DapE enzyme is a safe antibiotic target whose potential in the field of antibiotics is not fully explored. In the dinuclear Zn (II) form obtained from haemophilus influenzae, the dimeric DapE enzyme requires two Zn (II) ions per mole of polypeptide for enzymatic activity [2]. Recent studies have also shown metal promiscuity in enzyme activity of DapE. We have used QM/MM methods to carry out the binding affinity of substrates in the presence of different metal centres. In this work, we will present our ongoing research on the role of metal centres in substrate binding and catalysis by DapE enzyme.

Exploring structural requirements for the selective inhibition of tumor associated human carbonic anhydrase IX: a comparative in silico study

Varun Chahal, Rita Kakkar*
Computational Chemistry Laboratory, Department of Chemistry, University of Delhi, Delhi-110007, India
Presenting Author: chahal.varun94@gmail.com
* rkakkar@chemistry.du.ac.in

Human carbonic anhydrase IX (hCA IX) is overexpressed in many tumor types and serves as an important target for the discovery of novel anticancer agents. However, developing compounds that can selectively inhibit hCA IX over the widespread cytosolic isoform, human carbonic anhydrase II (hCA II), is a major challenge. Hence, efforts need to be focused on developing selective hCA IX inhibitors. This work focuses on recognising structural features of hCA IX receptor that would help in achieving its selective inhibition. Protein structure alignment have been performed to map the structural differences between the receptors. Further, rigid as well as flexible docking followed by density functional theory calculations and molecular dynamics simulations on SLC-0111, a selective hCA IX inhibitor, have been carried out for both the isoforms and the receptor-ligand interactions responsible for selective inhibition have been characterized. Based on this, residues responsible for these interactions have been marked. Molecular docking and binding energy calculations for three different series of SLC-0111 analogues have been carried out and their interactions with the hCA II and hCA IX receptors have been established. Thus, based on receptor-ligand interactions, molecules showing high potency and selectivity toward hCA IX have been identified.

(1) Department of Chemistry, Indian Institute of Technology Kanpur, Kanpur India

(2) Centre for Lasers & Photonics, Indian Institute of Technology Kanpur, Kanpur, India

* amitkm@iitk.ac.in

Alcohols are widely used in the industry depending upon their physical and chemical properties as a solvent, ingredients in cosmetics, medicine & fuel. Time-resolved thermal lens spectroscopy is a highly sensitive spectroscopic method for investigating the photo-thermal properties of chemicals.[1] Its principles are based on the localized heat accumulation due to the contactless heating by a laser beam. The laser-induced heating effectively modulates the refractive index inside the sample and makes it act like a lens.[2] Mode mismatched Pump-Probe spectroscopic method was employed the thermally induced nonlinear optical properties of methanol and its surfactant (oleic acid) loaded mixtures. As found, Methanol has a much higher Thermal signal (TL) as compared to oleic acid (OA). Due to its unique characteristic, Methanol is found to be capable of rapid convective heat transfer.[3] We study the variation of TL signal of Methanol with different loading ratios of (OA) surfactant in the mixtures. Experimental findings indicate that the TL signal of the mixture significantly increases to up to an optimum loading of OA. This was attributed to the increased ratio of the OA (bigger size molecule compared to Methanol) in the mixture. The easily drifting of methanol molecules is restricted due to the induction of bigger surfactant molecules, which eventually leads to an increasing TL signal.

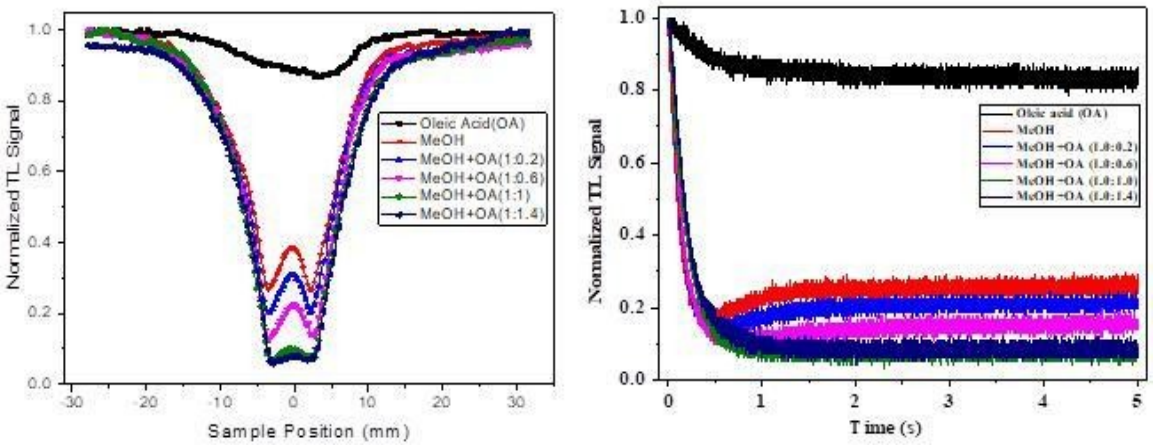

Fig. 1: TL Signatures of methanol and surfactant loaded mixtures

Correlation Effects in the Photoelectron Spectrum and Photoionization Dynamics of OsO_4

Soumitra Manna, Dr. Sabyashachi Mishra
Indian Institute of Technology Kharagpur, Kharagpur,India
mannas973@gmail.com

The experimentally recorded photoelectron spectra of OsO_4 exhibit five distinct bands with varying intensities. Correct assignment of these vibronic bands requires an accurate treatment of the electronic structure and correlation in the cationic species. In this presentation, we would present a comparative account of different electronic structure methods (such as, EOM-CCSD and CASSCF) in the presence of spin-orbit coupling to provide an assignment of the experimental photoelectron bands. While both EOM-CCSD and CASSCF methods could describe the low-lying electronic states of the cation accurately, the high- energy excited states demand a multi-reference treatment with an expanded active space. That apart, the origin of spin-orbit coupling in different electronic states and their consequence in the experimental spectra will be discussed. By analysing the state of the ejected photoelectron, the photoionization cross-sections have been calculated for all photo- ionization channels that adequately explain the variation of cross-section with photon energy and the resonant structures in the experimental findings. The resonant structures have been explained by calculating the asymmetry parameters and from the wave function analysis of the ejected photoelectron. It will be shown that the resonant structures are prominent when the molecular orbitals are contributed by both metal and ligand orbitals.

Supercooled Liquid Inside Confined Environment

Anupama Sharma
Department of Computational Sciences, School of Basic and Applied Sciences, Central University of Punjab
anusharma.jan1995@gmail.com

The inhomogeneous behavior of water in confined environment presents an interesting field of scientific investigation because of its relevance with various biological systems and its application in the field of desalination processes, flow sensing and drug delivery system [1].

In this work we have studied the property of Water using TIP4P/2005 water model confined inside the arm-chair carbon nanotubes using Classical MD Simulation. This study includes the structural morphism that water shows inside the tube with varying diameter and temperature that ranges from 350K down to 100K. We have observed that water shows structural morphism for nanotubes greater than 1.2 nm but no specific structure was observed for tube greater than 1.2 nm at higher temperature as the hydrogen bonding is dynamic and the structure is not specific but absolutely there is pattern in the arrangement of water molecule which it follows once inside the tube and is dependent over the tube diameter, which on lowering the temp shows more of orderness leading towards structural refinement. Along with it, we have also observed drying transition at subzero temperature in a CNT of diameter greater than 1.2 nm that has been reported earlier via experiment [2].

Isothermal compressibility of basic α-Amino Acids in aqueous salt solutions at different temperatures.

Dr. Umaima Gazal
Assistant Professor, RBVRR Womens College (Osmania University), India
dr.umaimarbvrr@gmail.com

Density and speed of sound data have been employed for the calculation of isothermal compressibility values (κT) by using Mc-Gowan's relation. The κT values of (L-leucine / L- isoleucine / L-glutamine / L-alanine / glycylglycine + 0.512 mol·kg^{-1} aqueous K_2SO_4) solutions are less than those of (L-leucine / L-isoleucine / L-glutamine / L-alanine / glycylglycine + 0.512 mol·kg^{-1} KNO_3) solutions at all temperatures of study. The decrease in κT values with an increase in solute concentration seems to be a result of a corresponding decrease in free volume and the average kinetic energy of constituents of solutions. The internal pressure (Pi), solubility parameter (δ) and pseudo-gruneisen parameter (Γ) values also have been computed by using the values of κT obtained from Mc-Gowan's relation.

Keywords: Amino acids, salt effect, internal pressure, speed of sound.

In coment times, synthesis and spectroscopic studies on a series of substituted dibenzodioxins [1-6] have been performed by the experimental group of Banerjee.Computational studies on these systems were performed by Chattopadhyay and co-workers. These systems include the fluorescent dibenzodioxinswhere the dioxin ring is attached toaterephthalonitrile(1,4-dicyanobenzene) moiety on one side[1]. These moietie scan form donor-acceptor based fluorophores. Our studied terephthalonitrile compounds attached to cyclic diamine groups are found to be highly fluorescent. In fact, their attachment with the benzodioxinring also forms strongly fluorescent compound. However, introduction of a nitro group in the benzene ring (attached to dioxin) makes it almost non-fluorescent in spite of the presence of theterephthalonitrile moiety with attached cyclic amine group. Our computational studieshave revealed the presence of two different singlet excited state (S1) minima of the nitro compounds, one with a planar geometry and the other with a twisted-NO_2 group. In the planar excited state, the charge cloud in LUMO

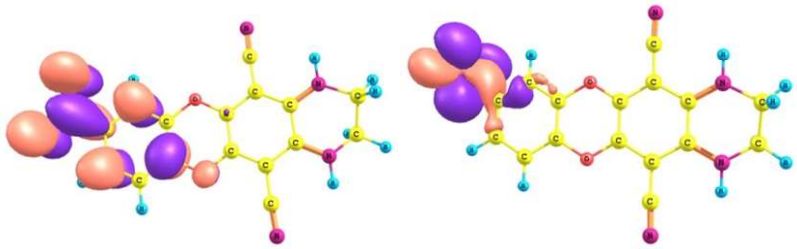

Figure 1. LUMO at the planar excited state (S1) geometry (left) and LUMO at the NO_2-twisted excited state (S1) geometry (right) is shifted (Figure 1) towards the nitrobenzene ring while in the twisted –NO_2 excited state geometry, the charge is completely shifted towards the nitro group. The latter geometry is characterized by low energy gap between the S1 and S0 states, indicating an internal conversion channel (IC) which is likely to be responsible for its non-fluorescence property. The transition state connecting these two geometries has been optimized and it shows that the energy barrier to form the twisted-NO_2 minimum is around 7 kcal/mol. We have also investigated the possible role of intersystem crossing (ISC) along the nitro twisting coordinate of the S1 state.Interaction of the triplet states with the S1 state along the nitro twist path (<C-C-N-O dihedral angle) starting from the planar geometry has been noticed. This

indicates a possible population transfer to the triplet states from the S1 state and thereby reducing the fluorescence.

Responses of Oryza sativa L. towards azo functionalised Schiff base Cu(II) complexes and $CuSO_4$: A comparative morphological and biochemical study

Kaushik Acharjee and Biswajit Sinha*
Department of Chemistry, University of North Bengal, Darjeeling, West Bengal, India-734 013
* kashacharjee@gmail.com

Azo fuctionalised Schiff base ligands having N_2O_2 donor binding sides are capable of forming metal complexes and can be used as potential plant micronutrient supplier. Two different ligands and their copper complexes were synthesised by conventional protocols and then characterised by both spectroscopic and elemental analysis. Investigations were done by taking rice seeds as plant material. Various growth and biochemical parameters were monitored by taking different concentrations of $CuSO_4$, prepared ligands and Cu(II) complexes. Analysis of various biochemical results reveals that Schiff base Cu(II) complexes have less toxic effects than copper sulphate on rice seedlings and thus facilitates better tolerance to copper toxicity than copper sulphate.

Keywords: Plant growth; Cu(II) chelates; copper toleranc; azomethine group.

There is a growing concern that the presence of pharmaceuticals in water bodies and in drinking water adversely affect thehealth and behaviorof human and wildlife, including insects, fish, birds, and more.[1] They have become the chemicals ofan emerging threat to the public. While wastewater treatment plants would normally take care of such a situation but pharmaceuticals, in general, pass through. In this regard, extensive research efforts have been focused on improving existing water treatment technologies and developing new advanced oxidation technologies. Although semiconductor photocatalysts, e.g., titania, showing potential for such purpose, they suffers from high electron-hole recombination rate, low surface area, and limited light absorption properties. On the otherhand, photoexcited titania in contact with carbon displays efficient charge separation by sinking photogenerated electrons.[2] In this context, ordered porous titania (TMP-123) with their unique textural, electronic, and optical properties is highly relevant[3,4] and thatthe titania-carbonnanocomposites exhibiting 2D-hexagonal mesoporous framework structure (Fig. 1 a-d) and high surface areashow much promise compared to the commercial titania (P-25) which exhibits particulate-like morphology (Fig. 1e). Thus, we observedan excellent degradation efficiency (DE) of famotidine (FAM) by the integrated titania-carbon photocatalysts (Fig. 1g), which is further confirmed by HPLC studies (Fig. 1h). The catalyst, viz., TMP-123/CMK-3, is superior to all others in terms of FAM mineralization, which could be attributed to excellent electron sinkbehaviour of CMK-3, i.e., low charge transfer resistance deducedfrom Nyquist plot (Fig. 1i) and facile interface characteristics of titania-carbon composite as inferred from Mott–Schottkyplot (Fig. 1j).

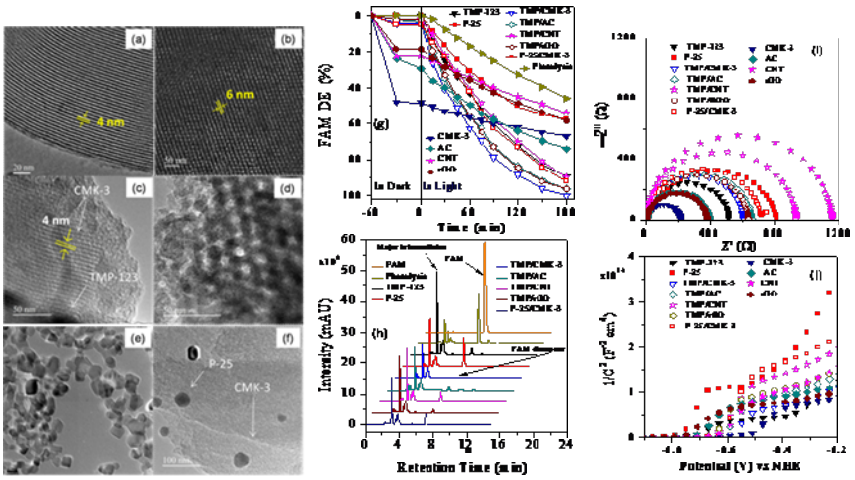

Fig. 1. TEM images of CMK-3 (a), TMP-123 (b), TMP-123/CMK-3 (c & d), P-25 (e), and P-25/CMK-3 (f). Potocatalytic degradation of FAM (g). HPLC profiels at 180 min (h). Nyquist plot(i). Mott–Schottkyplot (j).

An Intrinsically Disordered Protein in F127 Hydrogel: Fluorescence Correlation Spectroscopy and Structural Diversity of Beta Casein

Ushasi Pramanik, Subhajit Chakraborty, Kankan Bhattacharyya*, Saptarshi Mukherjee*
*Corresponding Author E-mail: kankan@iiserb.ac.in, saptarshi@iiserb.ac.in

Intrinsically Disordered Proteins (IDPs) can acquire one of the many possible local minima due to their rapid conformational fluctuation which prevents them from folding and functioning. Thus IDPs have a flat free energy surface and hence they cannot be crystallized.[1] However, many experimental and theoretical findings reported that macromolecular crowding (~400 mgL^{-1})can trigger the disorder-to-order transition depending on the 'metaphysics' of IDPs.[2] Pluoronic copolymer F127 can act as 'smart polymer' and is used often as crowding agent to create cell like milieu.[3] To observe the dynamics inside the crowding hydrogel, we covalently probed an IDP bovine beta-casein (β-CN) with Alexa488. The conformational analyses by Circular Dichrosim (CD) revealed that β-CN has become ordered inside hydrogel. Fluorescence Correlation Spectroscopy (FCS) suggestedthe structural fluctuationbetween a highly extended state (radius 34.5 nm) and a highly collapsed state (radius 1 nm).[4] Moreover, we showed that inside the crowding environment, β-CN is located at the corona region of the spherical micellar aggregates by exposing to the void region of the gel with translational viscosity 10-16 times higher than buffer.The local rotational viscosity in the corona region of F127 gel is ~2-times higher compared to the buffer as obtained from anisotropy studies.[4]

Synthesis of Dual Reactive Hollow Micron/ Sub-micron Capsules

Angana Borbora, Uttam Manna*
Department of Chemistry, Indian Institute of Technology Guwahati, Guwahati, India
Assam-781039.
borboraangana@gmail.com

Multilayered microcapsulestailored with different desired chemical functionalities are of particular interest due to their potential application in confining various cargo, liquid crystal, and bioactive enzymes for the various relevant applications. One of the promising methods for the fabrication of hollow microcapsules is layer-by-layer (LbL) assembly of multilayer films onto colloidal particles followed by selective core removal. Among the available fabrication methods, this method hasthe advantages of precise control over the size, shape, wall thickness, composition, and functions of the resulted hollow microcapsules. Mostly, weak hydrogen bonds, disulfide bonds, and electrostatic interactions between two distinct polymers wereused in synthesizing multilayered microcapsules. In our approach, a single polymer derived covalently crosslinked microcapsule loaded with dual-reactive residual functional groups-acrylate and amine, is synthesized by a facile LbLdeposition process and a catalyst-free 1,4-conjugate addition reaction at ambient condition. Further, this single polymer derived microcapsule is tailored with different desired functionalities using various selected nucleophiles and electrophiles, following two independent reaction pathways at ambient conditions.[1]

A theoretical investigation of the structural, electronic and optical properties of the retrochalcones isolated from liquorice

Ankit Mittal, Rita Kakkar*
Computational Chemistry Laboratory, Department of Chemistry, University of Delhi, Delhi-110007, India
ankitmittal070@gmail.com
* rkakkar@chemistry.du.ac.in

Retrochalcones are known to exhibit a wide range of biological applications. The present work reports the theoretical investigation of six retrochalcones, namely echinatin, licochalcone A, B, C, D and E, isolated from liquorice. All the calculations have been performed using density functional theory at the B3LYP/6-311++G** level in the gas phase and in aqueous solution. The non-linear optical properties were computed and compared with the standard molecules, urea and *para*-nitro aniline. Further, the mono, di and tri-anionic forms have also been studied to find out the sequential pK_a values corresponding to each hydroxyl group present in the considered compounds. Moreover, frontier molecular orbital analysis and molecular electrostatic potential maps were analyzed for a better understanding of the electro-optical properties of the compounds under study. Additionally, a number of global chemical reactivity descriptors have also been calculated.

Effect of Surface Charges on Nanoparticle (NP) -induced Molecular Reorganization of interfacial water at Model Cell Membrane

Preeti Gahtori
Research Scholar, Department of Chemistry, Indian Institute of Technology Roorkee, India
pgahtori@cy.iitr.ac.in

A depth understanding of NPs-cell membrane interaction is a key challenge because one has to probe the infinitesimally thin region comprising NPs and cell membranes. We have examined the role of electrostatics experimentally by using positively and negatively charged Au NPs, binding with negative charge lipid DPPG with vibrational sum frequency generation spectroscopy (SFG), a sub monolayer surface-/interface-sensitive techniqueand theoretically by molecular dynamicssimulation. After the injection of 15 nm anionic NPs to DPPG monolayer, SFG intensity of interfacial water molecules remain same whereas, injection of cationic NPs the intensity is abruptly decreases due to electrostatic attraction between cationic NPs and DPPG monolayer results in the replacement of some of interfacial water molecules from the interface to the bulk. Simulations results also support the experimental results. These results provide an overview of the interaction of NPs with lipid membranes which helps to evaluate the parameters that control the NPs membrane surface interactions for the design and application of NPs in future drugs and medicines.

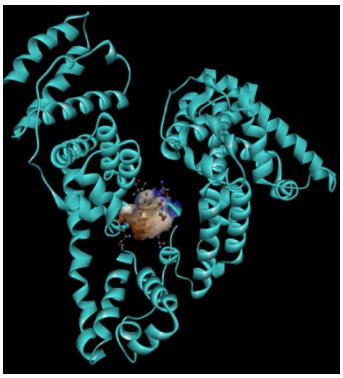
Study of Fluorescence Interaction and Conformational Changes of Bovine Serum Albumin with Histamine H_1-receptor–Drug Epinastine Hydrochloride by Spectroscopic and Time-Resolved Fluorescence Methods

Girish G. Ariga, Shivamurti A. Chimatadar*
Lecturer in P. G. Dept. of Chemistry, B. N. Degree College Dandeli 581325, Karnataka, India
girishariga@gmail.com

The fluorescence, ultraviolet (UV) absorption, time resolved techniques, circular dichroism (CD), and infrared spectral methods were explored as tools to investigate the interaction between histamine H_1 drug, epinastine hydrochloride (EPN), and bovine serum albumin (BSA) under simulated physiological conditions. The experimental results showed that the quenching of the BSA by EPN was static quenching mechanism and confirmed by lifetime measurements. The value of *n* close to unity indicated that one molecule of EPN was bound to protein molecule. The binding constants (K) at three different temperatures were calculated (7.13×10^4, 5.53×10^4, and 3.93×10^4 M^{-1}). Based on the thermodynamic parameters (ΔH^0, ΔG^0, and ΔS^0), the nature of binding forces operating between drug and protein was proposed. The site of binding of EPN in the protein was proposed to be Sudlow's site I based on displacement experiments using site markers viz, warfarin, ibuprofen, and digitoxin. Based on the Förster's theory of non-radiation energy transfer, the binding average distance, *r* between the donor and acceptor was evaluated and found to be 4.48 nm. The UV–visible, synchronous fluorescence, CD, and three-dimensional fluorescence spectral results revealed the changes in secondary structure of the protein upon its interaction with EPN.



Keywords: spectroscopic methods; epinastine hydrochloride; bovine serum albumin; time resolved fluorescence; circular dichroism

Molecular Dynamics Simulation of 6-Hydroxy-2-Thioxocoumarin Bound Human Carbonic Anhydrase II

Satyajit Khatua and Dr. SrabaniTaraphder*
Department of Chemistry, Indian Institute of Technology Kharagpur, Kharagpur-721302
satyajitkhatua@iitkgp.ac.in, srabani@chem.iitkgp.ac.in

Inhibition of the metalloenzyme carbonic anhydrase (CA) has a wide range of pharmacological applications. The molecular mechanism of inhibition of CAs is qualitatively understood for different classes of inhibitors binding to the metal centre. We focus in this work on a novel coumarin-based inhibitor, 6-hydroxy-2-thioxocoumarine (FC5, Figure 1) that does not bind to the metal centre. Instead, it has been reported experimentally to anchor to the zinc bound water (Zn-wat) molecule/hydroxide ion, leading to a high inhibition constant, $K_I > 100$[1]. However, the entry/exit mechanism of the ligand to/from the binding site of the enzyme is relatively unexplored. We report here computer simulation studies to identify the ligand unbinding path from the active site of the enzyme to the bulk solvent. Out of the six potential pathways identified for the unbinding of FC5 from the active site of HCA II, the ligand is found to unbind through the cleft formed by the loops between βC, βc and αC, αD. Our results resolve important enthalpic and entropic contributions of the protein during this unbinding process.

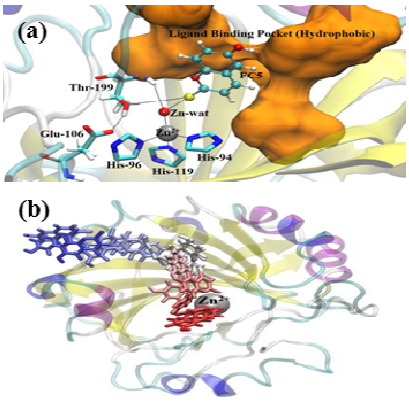

Figure 1.(a) Binding site of the ligand (FC5) which anchors to the zinc water/hydroxideion (PDB id: 4wl4[1]). Also shown are FC5 (CPK) in its binding pocket (shown in orangesurface) formed by Leu-198, Pro-202, Phe-131 and Val-121, Zinc ion (in gray colour), Zn-wat (red sphere) and Glu-106, Thr-199, three histidine residues bound to zinc (Licorice). (b) Unbinding pathway of FC5 from the active site of HCA II from SMD simulation.

Spectroscopic determination of proton affinities of Reserpine by Charge-Transfer complex formation

Bankim Chandra Ghosh
Government General Degree College, Singur, Jalaghata, Singur, Hooghly-712409.
bankimghosh@yahoo.co.in

From the charge transfer absorption spectra of a series of molecular complexes of reserpine (methyl-11,17α-dimethoxy-18β-[(3,4,5-trimethoxybenzoyl)oxy]-3β,20α-yohimban-16β-carboxylate) with*o*-chloranil, *p*-chloranil and DDQ, the individual proton affinities of its two N atoms have been determined in aqueous medium(containing 0.1%ethanol v/v). Variation of the CT spectra with pH was noted for this purpose. Necessary working formula was derived and utilized in the determination. The two proton affinities were also determined directly from the UV-vis absorption spectra of reserpine itself. The determined values were also checked by noting the variation of fluorescence intensity of reserpine upon addition of acid and base; the fluorescence spectrometric results agreed almost completely (within the limits of experimental error) with the absorption spectrometric results.

Keywords: Reserpine, Charge-Transfer Complex, Proton affinity.

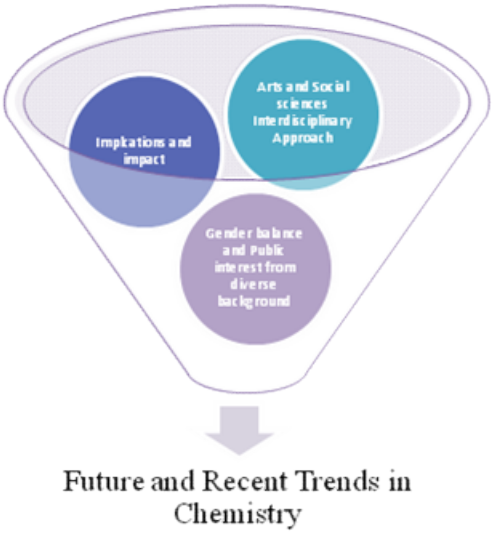
OP-2

Future and Recent Trends in Chemical Sciences

Dr. Meenakshi Virendra Rathi
SavitribaiPhule Pune University's RNC Arts,JDB Commerce,NSC Science College, Nashikroad, Nashik
meenakship2@gmail.com

The recent trends in innovation, and the challenges presented by the modern world, suggest that the word "pure" from "IUPAC" should be replaced. Chemistry can't be pure, and it needs to evolve – not only with its counterparts from the scientific domain, but also with arts and social sciences. This interdisciplinary involvement shall help identify new challenges, design new manufacturing processes, and understand the implications of Chemistry, hence making it a much more impactful subject.

The study of social trends - such as gender balance in chemical science education, interest from diverse backgrounds, inventions in chemical sciences, and the related challenges and opportunities - shall all help in the development of a new Chemistry community.New education policies will help universities to break boundaries and will incorporate the connection between different aspects of Chemistry and the traditionally transferable skills.



The role of chemical science should be to solve future challenges in cleanliness, food production, renewable energy, climate changes, drug discovery, and pharmacy; and also in building infrastructures. Education, training, social awareness, interdisciplinary approach, community building, gender equality, and overarching support from common people will hence make chemical science an influential toolin our quest to improve the everyday lives of people.

Effect of Plant Extract Composition on Green Synthesis of Silver nanoparticles

R. Khandelwal[a*], S.K. Arora[b], Chanchal Kachhawa[c]

[a]Government Women Engineering College, Ajmer, Rajasthan (India) [b]Smarat Prithiviraj Chouhan, Govt. College, Ajmer, Rajasthan (India) [c] Engineering College, Bikaner, Rajasthan (India)

*rakhi.gweca@gmail.com

In the past few years a lot of research has been done on the green synthesis of the silver nanoparticles using different plant extracts. In the present paper we focus our study on the synthesis of AgNPs by using *Glycyrrhiza glabra* and *Phaseolus vulgaris* extracts. The extract of roots of *Glycyrrhiza glabra* mainly contains saponin and plantestrogens while the seeds of *Phaseolus vulgaris* mainly contain proteins. Same method was adopted for the synthesis of AgNPs by these twoextracts.

Figure 1: Schematic presentation of green synthesis of AgNPs

It was observed that the both extracts are capable to reduce silver ions and synthesis of AgNPs took place with both the extracts. But the X-Ray diffraction studies reveals variation in size and phases of the synthesized AgNPs in eachcase.

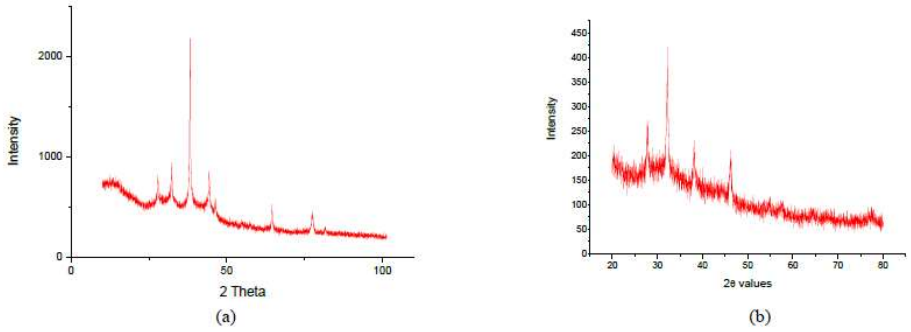

Figure 2: XRD Patterns of AgNPs synthesized by (a)*Glycyrrhiza glabra* and (b) *Phaseolus vulgaris* extracts respectively

The variation in the XRD patterns indicate that the chemical composition of plant extracts greatly affects the size and phases of the AgNPssynthesized.

Acknowledgement: The authors are grateful to TEQIP-III Rajasthan Technical University, Kota for providing financial assistance for this research work and also thankful to UGC-DAE-CSR Indore centre for providing XRD studiesfacility.

OP-4

Green Chemistry: Way of Sustainable Development

Hari Shankar Biswas
Assistant Professor , Department of Chemistry
Surendra Nath College, 24/2 M.G.road , Kolkata-09
E-mail: harishankarb7@gmail.com

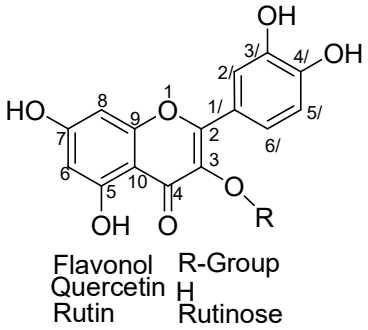
Basic Science in all its forms is elementary for human continued existence and growth. In particular, chemistry has always been connected with food chemistry, oils and paints, chemicals (for a variety of uses like cleaning products, leather processing, detergents, polymers, paper manufacture, printing, dyeing and much more). Above all chemistry serves as a common interface between practically all of the other sciences. This is the reason why green chemistry has been chosen to preserve the sustainability of all the processes. Sustainability largely depends on continuous consumption of large amount of natural resources, chemicals and energy, all these are largely non-renewable resources. Later along with the desired product, a large amount of waste is generated which is needed to be dumped and the best we can do is to dump it somewhere on land or in sea. But repeated consumption of resources and dumping of this waste is creating a serious problem to the sustainability of these production processes and ultimately to the survival of human race. Green chemistry is a very broad term that covers all the processes starting from fundamental research to production, to be done environmentally sustainable way and it protects our environment without harming growth and development. Howsoever beneficent green chemistry principles could be to sustainability, the sensible implementation in large production plants may be a daunting task, because it demands an enormous change in industrial setup, machinery and pilot plants. Awareness of a problem and controlling it is in itself the big leap required in implementing new policies. Under these circumstances there's a requirement to take care of balance between supporting new developments in chemistry and bringing the previously established chemical change under greener and sustainable purview. It is hoped that very soon a trend may get firmly established wherein most of the existing chemical processes could become greener and sustainable.

OP-5

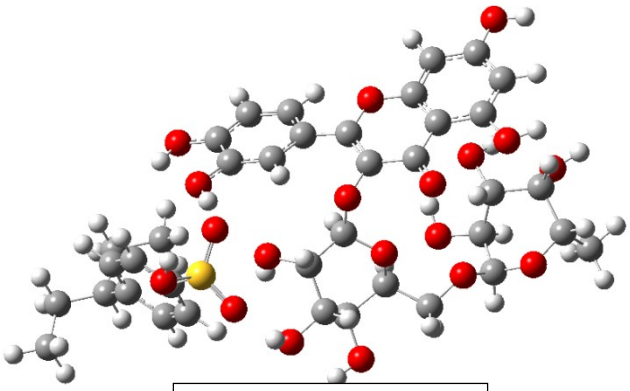
Adsorptive Separation of Quercetin and Rutin using Ion Exchange Resins: Experimental and Molecular Modeling study

Monali Dutta Saikia[a*]
[a]Department of Chemistry, Arya Vidyapeeth College, Guwahati – 781016, Assam, India
monalisaikia@hotmail.com

Two ion exchange resins, Dowex 1X4 chloride and Dowex 50WX8 are evaluated for selective adsorption or enrichment of flavonoid molecules such as quercetin and rutin from aqueous solution. These two flavonoids usually occur as mixtures in different plant resources, also commercially obtained rutin is contaminated with nearly 1 to 3% of quercetin. High purity rutin and quercetin are significantly required in pharmaceutical and food industries. It is observed that anion exchange resin has higher adsorption selectivity for quercetin over rutin. The effect of pH analysis confirms that a combined effect of molecular adsorption and ion exchange mechanism has taken place under alkaline conditions (at pH 11) but under acidic conditions (at pH 3) molecular adsorption is the only process of flavonoids uptake. Molecular modeling studies have supported the experimental observations on selective adsorption of quercetin and rutin from aqueous phase.



Flavonol	R-Group
Quercetin	H
Rutin	Rutinose



Rutin-Resin Interaction

Solvation dynamics in solvent free protein – polymer surfactant biomolecular assemblies

Tanuja Kistwal, Anasua Mukhopadhyay, Kamendra Sharma, and Anindya Datta*
Department of Chemistry, Indian Institute Of Technology Bombay, Powai, Mumbai 400076,India
* adutta@iitb.ac.in

Solvent-free proteins have attracted tremendous attention in recent times, due to its potential use as a green, nonaqueous solvent with low-volatility, for the synthesis of organic and inorganic compounds, as electrolytes, catalysis, etc.[1,2] While dynamics of dye-labelled HSA has been reported,[3] we focus on solvation dynamics of solvent-free protein, labelled with CPM (7-dimethylamino-3-(4-maleimidophenyl)-4-methyl-coumarin) dye to understand bound water dynamics. This study has been done using Fluorescence correlation spectroscopy (FCS) with a conformational dynamics model of data analysis and a comparative examination of hydrodynamic radii of different CPM labelled HSA modified systems. Solvent free causes blue shift in the emission maxima from CPM covalently bound to HSA. The average solvation time is increased from 700 ps (CPM bound to HSA) to 2 ns in the presence of solvent free CPM labelled HSA. FCS suggest that in a solvent free system, diffusion coefficient decreases, and hydrodynamic radius increases which implies larger protein size.

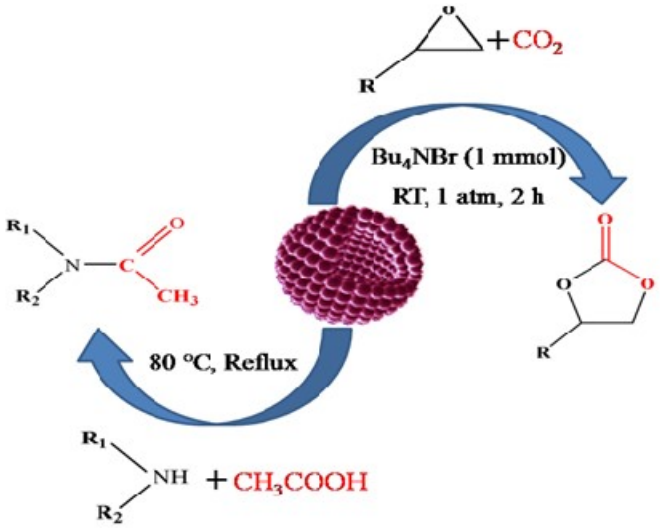
Morphology of ZnO triggered versatile catalytic reactions towards CO_2 fixation and acylation of amines at optimized reaction conditions

Atanu Sahoo
JRF, University of Calcutta
atanusahoo.chem@gmail.com

Hollow spherical ZnO particles with porous exterior surface are successfully synthesized and employed as a cost effective heterogeneous catalyst for CO_2 fixation in a wide range of epoxides at atmospheric pressure and room temperature to form cyclic carbonates. In fact, conversion of carbon-di-oxide into value aided chemicals is one of the major areas of contemporary research. This versatile material is also capable to catalyze acylation of amines in solvent free condition. The end products of both the reactions i.e. cyclic carbonate and N-acylated amines have huge industrial importance. The pristine ZnO nanomaterial without incorporation of metal nanoparticles has shown excellent reusability up to five consecutive reaction cycles without considerable loss in its efficiency which is quite encouraging for industrial realization.



OP-8

Order of kinetics computation for DTA (Differential Thermal Analysis) curve of some compounds using the concept of skewness

Bikash Kumar Sarkar
Department of Physics, Mrinalini Datta Mahavidyapith, Birati, Kolkata-700051, West Bengal, India
biku.mdm@gmail.com

Qualitative identification of organic and inorganic compounds can be made by using Differential Thermal Analysis (DTA) technique. Different kinetic parameters, like order of kinetics, activation energy and pre-exponential factor can be determined from the curves obtained from differential thermal analysis for different compounds. Order of kinetics, one of these important kinetic parameters, is related to the symmetry of a DTA curve. Symmetry of DTA curve which should be determined by using the longer portion of the curve, can be described by the skewness ( ) of the peaks. Skewness indicates the degree of asymmetry of distribution, value of which may be positive, negative or zero depending on the nature of distribution. Negative skewness is observed in first order DTA peaks whereas positive skewness is noticed in second order peaks. Skewness, therefore, can act as a good indicator of the order of kinetics of DTA peaks. In the present study, skewness of DTA curves resulted from kinetic order model (KOM) has been investigated. A novel attempt has been made to relate the skewness of a DTA peak with its order of kinetics. Finally, the present technique is applied to compute the orders of kinetics of some reported DTA curves of the compounds namely Georgia kaolinite, Eureka halloysite, RDX and TNT. The values of the orders of kinetics obtained in this method are found in fair agreement with those reported in literature.

OP-9

Surfactant and Polymer induced AIEE towards White Light Emission and Lipid Droplet Imaging

Soumyadipta Rakshit,[a]Sharmistha Das,[a]Anindya Datta[a]*
[a] Department of Chemistry, IIT Bombay, Powai, Mumbai – 400076
srakshit1987chem@gmail.com

Dimethyl-2,5-bis(4-methoxyphenylamino)terephthalate (DBMPT) is a water-insoluble fluorogenic molecule, which has been rendered water-soluble in physiological conditions, by the addition of nonionic triton X-100 (TX-100) and triblock copolymers (TBPs), P123 and F127. In the presence of TX-100DBMPT exhibits unidirectional aggregated growthto produce highly luminescent nanorods, the dimensions and emission intensities of which are controlled by concentration of DBMPT. Interestingly, shapes of the aggregates formed with the two TBPs are found to be very different, even though they differ only in the length of hydrophilic blocks. DBMPT-P123 aggregates are micrometer-sized and spherical, while DBMPT-F127 aggregates form nanorods.

Energy transfer from perylene-3,4,9,10-tetracarboxylic acid dianhydride (PTAD) to the nanorods formed in the presence of TX-100 in aqueous medium produces pure white light emission with the CIE chromaticity coordinates (0.33, 0.36) and a significantly high quantum yield of 35%. Gelation of the system with agarose yields a bright white light emitting gel, demonstratingit's excellent potential towards light harvesting and in organic electronic devices.

In case of DBMPT-F127 nanorods excellent cell permeability is observed, in contrast to DBMPT-P123 microspheres. These fluorescent nanorods exhibit the ability to mark lipid droplets within the cell and hence bear the promise for application in intracellular imaging.

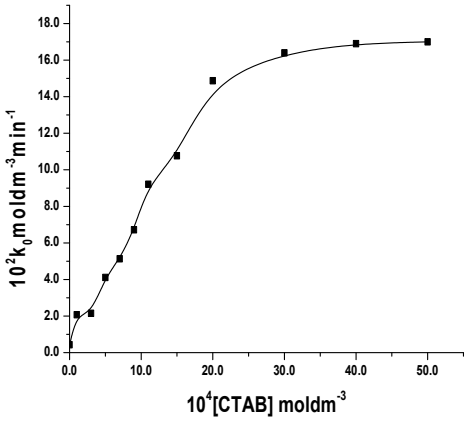
Effect of cetyl trimethyl ammonium bromide and sodium dodecyl sulphate on oxidation of indigo carmine with potassium peroxy diphosphate- A Kinetic and Mechanistic study

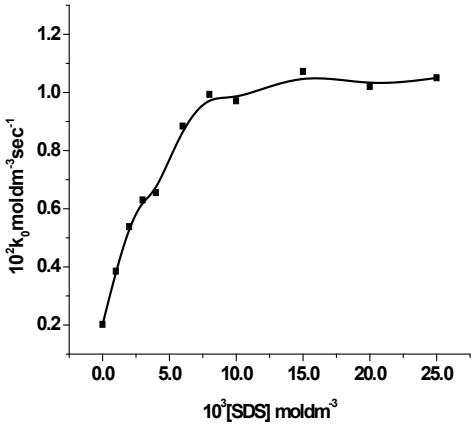
Kalyana Chakravarthy Mutnuru
Anil Neerukonda Institute of Technology & Sciences,Visakhapatnam
chakravarthy.chemistry@anits.edu.in

The oxidation of indigo carmine(IC) with potassium peroxy diphosphate (PDP) in absence and presence of cationic CTAB and anionic SDS micelles is investigated. The investigation is done in aqueous sulphuric acid medium by maintaining the ionic strength at 3.0 moldm^{-3} .The stoichiometry of the reaction is reported as 1:1 using mole ratio method. The pseudo zero order constant is determined from the linear plots of absorbance versus time under the conditions [IC] < [PDP].The reaction shows zero order kinetics with respect to varying[IC], first order kinetics with respect to varying [H^+] and [PDP] in absence and in presence of micelles. The reaction rate is accelerated with varying [CTAB] and [SDS] and reached a limiting value. The rate [surfactant]-profile has limiting nature which shows that the reaction is unimolecular micellar reaction.The binding constant of peroxy diphosphate is determined with CTAB and SDS micelles by applying Berezin treatment to the kinetic data. The kinetic equation in aqueous medium is reported as

$$-\frac{d[IC]}{dt} = k_1 K_2^1 [PDP]_t [H^+]$$



Effect of [CTAB] micelle on rate



Effect of [SDS] micelle on rate

OP-11

Molecular Interactions of L-Aspartic Acid and L-Glutamic Acid in Aqueous Benzyl Tri-Methyl Ammonium Chloride Ionic Liquid Solutions at Different Temperatures

Dr. Anuradha Sinha[1] and Prof. Mahendra Nath Roy[2]
[1]Department of Chemistry, Islampur College, Islampur, Uttar Dinajpur-733202, West Bengal, India.
rinky_027@rediffmail.com,
[2]Department of Chemistry, University of North Bengal, Darjeeling-734013, West Bengal, India.
mahendraroy2002@yahoo.co.in

L-Aspartic and L-Glutamic acid (two solute molecules) interact with an ionic liquid (Benzyl tri-methyl ammonium chloride) in aqueous medium. The interactions have been explained on the basis of parameters (apparent molar volume, viscosity B-coefficient, molar refraction, specific conductance) at different temperatures and different concentrations from density, viscosity, refractive index, conductance measurements, respectively. Using Masson equation, the experimental slopes and the limiting apparent molar volumes are obtained which explain the solute-solute and solute-solvent interactions. Viscosity parameters, A and B obtained from Jones-Doles equation explained the solute-solute and solute-solvent interactions in the solution. Molar refraction has been calculated from the Lorentz-Lorenz equation. The specific conductance also explained the interaction properties.

It provides the information about ion-dipole interaction and show that the solute-solvent interaction between BTAC ionic liquid and L-Aspartic acid and L-Glutamic amino acid systems is higher than the solute-solute interaction. This is resulted by hydrophobic interactions which lead to volume contraction. The physico-chemical methodologies, describes the mode of interaction in solution. The values of $(\delta\Phi E0/\delta T)P$ and (dB/dT) have been calculated to provide the information that the solute–solvent interaction is structure-making. The extent of solvation is found to be highest in L-Glutamic acid at 0.05m 313K and lowest in L-Aspartic acid at 0.01m 293K.

OP-12

Kinetics and mechanism of the oxidation of some α-hydroxy acids by 2-picolinium chlorochromate

Divya Chandora* , Devendra Kumar and Anurag Choudhary
Chemical Kinetics Laboratory, Department of Chemistry, J.N.V. University, Jodhpur (Rajasthan)
anurag051981@gmail.com

The oxidation of glycollic, lactic, malic and a few substituted mandelic acids by 2-picolinium chlorochromate (PICC) in dimethylsulphoxide (DMSO) leads to the formation of corresponding oxoacids. The reaction is first order each in PICC. Michaelies-Menten type of kinetics is observed with respect to the hydroxy acids. Reaction is failed to induce the polymerisation of acrylonitrile. The oxidation of α deuteriomandelic acid shows the presence of a primary kinetic isotope effect (k_H/k_D = 5.79 at 298 K). The reaction does not exhibit the solvent isotope effect The reaction is catalysed by the hydrogen ions. The hydrogen ion dependence has the form: $k_{obs} = a + b [H^+]$. Oxidation of p-methyl mandelic acid has been studied in 19 different organic solvents. The solvent effect has been analysed by using Kamlet's and Swain's multiparametric equations. A mechanism involving a hydride ion transfer via a chromate ester is proposed.

Keywords: Correlation analysis, dichromate, hydroxy acids, kinetics, mechanism, oxidation

Correlation Analysis of Reactivity in the Oxidation of Some Vicinal and Non-Vicinal Diols by Morpholinium Fluorochromate

Jigyasa Sharma*, Ambika Singadiya and Vinita Sharma
Department of Chemistry, J N V University, Jodhpur 342 005, INDIA
drpkvs27@yahoo.com

The kinetics of oxidation of four vicinal, four non vicinal diols by Morpholinium fluorochromate (MFC) have been studied in dimethylsulphoxide (DMSO). The main product of oxidation is the corresponding hydroxycarbonyl compound. The reaction is first order each in MFC. Michaelies-Menten type of kinetics is observed with respect to the diols. The reaction is catalysed by hydrogen ions. The hydrogen ion dependence is taking the form: kobs = a + b[H^+]. The oxidation of [1,1,2,2 $2H_4$] ethanediol exhibits a substantial primary kinetic isotope effect (k_H/k_D = 5.73 at 298 K). The reaction has been studied in nineteen different organic solvents and the solvent effect has been analysed using Taft's and Swain's multiparametric equations. The temperature dependence of the kinetic isotope effect indicates the presence of a symmetrical transition state in the rate determining step. A suitable mechanism has been proposed.

Keywords: Correlation analysis, Diols, Halochromates, Kinetics, Mechanism, Oxidation

Oxidation of some Unsaturated Acids by Pyridinium Dichromate: A Kinetics and Mechanistic Study

Varsha Bishnoi*, Pramilla Bishnoi, Pradeep K. Sharma and Om Prakash
Chemical Kinetics Laboratory, Department of Chemistry, J.N.V. University, Jodhpur – India
drpkvs27@yahoo.com

The oxidation of maleic, fumaric, crotonic and cinnamic acids by pyridinium dichromate (PDC) in dimethylsulphoxide (DMSO) leads to the formation of corresponding epoxide. The reaction is of first order with respect to PDC and the acid. Due to non-aqueous nature of the solvents toluene-p-sulphonic acid (TsOH) was used the source of hydrogen ions. The reaction is catalysed by hydrogen ions. The hydrogen-ion dependence has the form: $k_{obs} = a + b [H^+]$. The oxidation of these acids was studied in nineteen different organic solvents. The solvent effect was analyzed by Kamlet's and Swain's multiparametric equations. Solvent effect indicated the importance of the cation-solvating power of the solvent. A mechanism involving a three-centre transition state has been postulated.

Keywords: Halochromates, kinetics, mechanism, oxidation, unsaturated acids.

laxminj2755@gmail.com

The kinetics of ruthenium(III) catalysed degradative oxidation of methylparaben by the copper complex, diperiodatocuprate(III) in alkaline medium is studied at 298 K and at a ionic strength of 8.0×10^{-2} mol dm^{-3}. In the presence of catalyst ruthenium(III), the reaction between methylparaben and diperiodatocuprate(III) in aqueous alkaline medium exhibits 1:1 stoichiometry. The oxidation products were identified by UV-visible, GC-MS and IR spectroscopy. The reaction exhibited unit order in case of diperiodatocuprate(III) and ruthenium(III) concentrations, while less than unit order with respect to methylparaben and alkali concentrations. The added periodate retard the rate of reaction. The effect of added products, ionic strength and dielectric constant on the rate of the reaction were studied. The active species of diperiodatocuprate(III) and ruthenium(III) in alkaline media are $[Cu(H_2IO_6)(H_3IO_6)]^{2-}$ and $[Ru(H_2O)_5(OH)]^{2+}$ respectively. The activation parameters with respect to the rate determining step and the thermodynamic quantities with respect to the equilibrium steps are evaluated and discussed. The plausible mechanism in consistent with the experimental results is proposed and discussed in detail.

Keywords: Kinetics, oxidation, diperiodatocuprate(III), ruthenium(III), methylparaben

Studies on the Oxidation of Aliphatic Primary Alcohols by Quinolinium Dichromate: A Kinetic and Mechanistic approach

Arpita Vyas*, Anurag Choudhary and Vinita Sharma
Chemical Kinetics Laboratory, Department of Chemistry, J.N.V. University, Jodhpur, – (Rajasthan) India
drpkvs27@yahoo.com

The oxidation of nine aliphatic primary alcohols by quinolinium dichromate (QDC) in dimethylsulphoxide leads to the formation of corresponding aldehydes. The reaction is first order with respect to QDC. A Michaelis-Menten type kinetics is observed with respect to alcohols. The reaction is promoted by hydrogen ions; the hydrogen-ion dependence has the form k_{obs}= a +b[H^+]. The oxidation of [1,1-$^2H_2$]ethanol ($MeCD_2OH$) exhibits a substantial primary kinetic isotope effect (k_H/k_D = 5.70 at 298K). The reaction has been studied in nineteen different organic solvents. The solvent effect was analysed using Taft's and Swain's multiparametric equations. The rate of oxidation is susceptible to both polar and steric effects of the substituents. A suitable mechanism has been proposed.

Unactivatedaziridines are fascinating sub-structures in a plethora of bio-active natural products, as well as these molecules undergoes various transformation as ring opening with different nucleophiles under mild reaction condition and furnished several important synthetic intermediates like amino-alcohol, di-amines, and azido-amines. Unlike activated aziridines, Synthesis of unactivatedaziridines is far more challenging task for the organic chemists. Herein we describe the direct methods for the synthesis of unactivated (N-H/N-Me) aziridines from alkenes, using *O*-(Sulfonyl)hydroxylamines as the aminating agent, Rh(II) catalyst in 2,2,2-trifluroethanol (TFE) as a solvent (Scheme 1).[1]

Molecular Water Oxidation Catalyst(s): An Approach for Predicting the Efficiency

Himangshu Pratim Bhattacharyya[1] and Manabendra Sarma[1]
Department of Chemistry, Indian Institute of Technology Guwahati, Guwahati 781039, India
himan176122114@iitg.ac.in

In the global scenario, energy crisis is one of the major concern. Although many renewable and non-renewable sources of energies were there, but they were not sufficient to meet the global energy demand. Given the abundance of sunlight and water and following its effective utilization, harvesting of water is one of the possible solution to fulfill energy demands in the presence of catalysts. The efficiency of the catalyst is the prime factor for delivering the higher conversion. With the aim of doing so, in this work, we developed a method theoretically, involving thermodynamic and kinetic study to predict the efficiency of molecular water oxidizing catalysts (MWOC) that corroborating to the previous experimental results. We hope, our method will help the scientific community to predict the efficient catalyst before proceeding to the mechanistic details.

Different α-Hydroxy Acids Oxidation By Benzimidazolium Fluorochromate: A Kinetic And Mechanistic Study

Bhawana Arora and Dr Pallavi Mishra*
Department of Chemistry, J N V University, Jodhpur 342 005, India,
arora.bhawana2012@gmail.com

The oxidation of glycollic, lactic, malic and some substituted mandelic acids by benzimidazolium fluorochromate (BIFC) was studied in dimethylsulphoxide (DMSO). Main product of oxidation was the corresponding oxoacids. The reaction was first order in relation to the BIFC and exhbited Michaelies-Menten type kinetics with respect to hydroxy acids. The polymerisation of acrylonitrile showed no effect on the reaction rate. The oxidation of α-deuteriated mandelic acid has been showed the presence of primary kinetic isotope effect i.e. (k_H/k_D = 6.15 at 25ºC). The solvent isotope effect has not been observed. The hydrogen ions were used to catalysed the reaction. The form of hydrogen ion dependence was: $k_{obs} = a + b\,[H^+]$. The multiparametric equations of Kamlet's and Swain's have been used to analysed the solvent effect. Mechanism involving the transfer of hydride ion via chromate ester has been tried to propose.

Keywords: BIFC, α-Hydroxy acid, Kinetics, Oxidation and Mechanism.

DNA binding studies of Tetrahydrocannabinol (Active Principle of Cannabis) using computational approach

Palak Sharma, Kumud Pandav and Prateek Pandya*
Amity Institute of Forensic Sciences, Amity University Uttar Pradesh, Noida
Department of Biotechnology, Indian Institute of Technology, Roorkee, Roorkee, India
ppandya@amity.edu

Tetrahydrocannabinol (THC) is the most abundant and major psychoactive drug present in Cannabis sativa. It is known for their anti-cancer effects. In this paper, we have attempted to identify and compare any possible binding interactions of THC with normal and methylated DNA sequences. This work has the potential to contribute in the fight against antiviral, antibacterial and many other diseases. The study has revealed that THC binds in the minor groove of both normal and methylated DNA. On comparing their binding energy, it is demonstrated that the binding energy with normal DNA is $\Delta G = -6.28$. Whereas, the binding energy with methylated DNA is $\Delta G = -6.07$. The binding of THC with normal DNA is found to be higher than that of methylated DNA. The structural details of binding of THC have also been disclosed which includes multiple hydrogen bonds, Vander Waal interactions, etc.

Modeling Single-Nanoparticle Catalysis

Subham Pal
IIT Madras
cy18d031@smail.iitm.ac.in

Nanoparticle catalysis is intrinsically heterogeneous, and hence challenging to study in ensemble measurements. Single-molecule detection of fluorogenic reactions in which a catalytic conversion of non-fluorescent substrates (off states) to fluorescent products (on states), occurring one at a time on the surface of a single nanoparticle, captures intrinsic heterogeneity in catalytic cycle in terms of stochasticity in the waiting times between two consecutive off and on signals [1-4]. In this work, we show how a unified theoretical framework, based on the chemical master equation (CME), provides a novel way to infer catalytic mechanisms and rate parameters from different, seemingly unrelated, measures introduced in a series of experimental studies on single-nanoparticle catalysis [1-4]. Building on aprevious work [5], we find that a Langmuir-Hinshelwood (LH) like mechanism is consistent with experimental data, provided it includes two important aspects ofintrinsic heterogeneity at the single-molecule level, namely, fluctuations due to surface restructuring dynamics and multiplicity of catalytic sites [6]. For this, we propose a parallel-pathway LH mechanism with replicas. This mechanism, in its minimal form, provides excellent quantitative agreement with experimental data, and shows how the sign and magnitude of waiting time correlations between consecutive turnovers provides a sensitive indicator of intrinsic heterogeneity. Our work establishes that the statistical dependences of off and on signals in a single turnover, and temporal correlations between consecutive turnovers are crucially linked with multiplicity of catalytic sites. Thisrules out all previous single-site models of single-nanoparticle catalysis in which statistical independence of off and on signals is implicitly assumed [1-5].

The most interesting non-stoichiometric oxides are found in transition metal and rare earth oxides at higher temperatures. The role of solid State properties in the catalysis using mixed metal oxide as catalyst have wide application In fertilizer, Petro-chemical , Pharmaceutical, cosmetic, paint detergents, plastic and food-stuff industries and these are also resistive towards acids and alkalies [2-6] The use of catalyst has opened up new process routes or revolutionsed the existing process in terms of economics and efficiency and has radically changed the industrial scenario. The use of catalyst is so pervasive today that nearly 70% of modern chemical processes are based on it at some stage or other and 90% new processes developed are catalytic nature. A series of non-stroichiometric spinel type of oxide catalyst of Praseodymium with cobalt and nickel were Synthesized by their oxalates through Solid State reaction technique at different activation temperatures i.e. 600, 700, 800 and 900°C. The characterization of catalyst was done by XRD. FTIR and ESR methods. X-ray powder diffraction study shows that catalysts are made up of well grown crystallinities decomposition of oxalate ion from the Catalyst. The kinetic decomposition of Urea was employed as a model reaction to study the catalytic potentiality of different catalysis. Surface and catalytic Properties of catalytic were measured. A relation between activation temperature and surface properties like excess surface oxygen (E.S.O.) Sutface aciditu and Surface area was observed. A Linear relationship between the surface area od the catalyst and the amount of ammonia gas evoled per gm of the sample was observed also. Nickel containing catalysts were found a bit more catalytic active in comparison to cobalt oxide catalysts. Transition metal ions (i.e. Ni(2+) & Co(2+) ions) are mainly responsible for catalytic potentiality of the catalysts. The Presence of transition metal ions in divalent state (+2 state) is confirmed by ESR study. Inner transition metal ion i.e. pr^{3+} ion moderates the catalytic activit. Frequency factor and activation energy involved in the process were also determined.

Expired Drugs: Eco-friendly Corrosion Inhibitors for different metals and alloys

Gita Rani[1] & Amit Kumar Nunach[2]
[1]Associate professor, Department of Chemistry, Chaudhary Devi Lal University, Sirsa, Haryana, 125055, India
[2]Research Scholar, Department of Chemistry, Chaudhary Devi Lal University, Sirsa, Haryana, 125055, India
nunachamit@gmail.com

Eco-Friendly approach in industries and research is the demand of current time. Expired drugs can play an important role in this context. After passing the expiry date, drugs are disposed off and causes the environmental pollution. However many researchers found that expired drugs are excellent corrosion inhibitors for different metals. Potentiodynamic polarization, Electrochemical Impedance Spectroscopy (EIS) and weight loss studies found Paracetamol, Tramadol, Moxifloxacin, Betnesol and many more with greater corrosion inhibition efficiency for different metals and alloys. It is interesting to know that some drugs retain their molecular integrity upto 10 years even after the expiry date. Hence the recycling of expired drugs could be economic and environment friendly for corrosion inhibition as well as for other research purposes.

Poster Presentation

Electroorganic syntheses: an alternative method for preparation of copper salicylate

Dr. Shreya Gorai
Faculty St. Xavier's college, Ranchi
shreyagorai.gorai@gmail.com

Electroorganic chemistry is a combination of two major branches of chemistry, namely electrochemistry and organic chemistry. It is a unit process in which complex is synthesized from electron transfer reactions across the electrode /solution interface. The electroorganic synthesis of copper salicylate is a green methodology to evaluate their coordination and biological activity. This methodology emphasis advantages over conventional chemical method because of its product specificity, high yielding and using current as cheapest of other energy source. It makes use of the universal chemical reagent- the electron which is contributes to control pollution.

In this study it evaluates the synthesis and characterization of copper salicylate which is prepared by electrochemical method. Copper salicylate are well known class of drugs that are antiviral, analgesic, antiproliferative, antipyretic and anti-inflammatory agent. It is used in clinical practice of inflammatory disorders including cancer, arthritis as well as for prevention of myocardial infraction. Over the past few years, there have been many reports on their application in radiopharmaceutical drugs. Organic electrosynthesis has been recognized as new reactor for industrial revolution in recent years.

Study On Reaction Between Lauric Acid And Lauryl Alcohol Catalysed By Molecularly Imprinted Polymer

Sumbita Gogoi
Assistant Professor, Department of Chemistry
Dergaon Kamal Dowerah College, Dergaon, Golaghat, Assam, PIN-785614
sumbita_gogoi@yahoo.co.in

Molecular imprinting is now becoming an emerging technology for preparation of polymers with specific molecular recognition properties. Molecularly imprinted polymers have catalytic active sites for which these polymers possesses the enzyme like catalytic behavior and can catalyze a large variety of reactions. In order to understand the enzyme like catalytic behavior of molecularly imprinted polymers, the esterification reaction between lauric acid and lauryl alcohol was carried out by systematic variation of substrates and polymer. The molecularly imprinted polymer used in this study is based on cross-linked polymerization of methacrylic acid with 4-aminopyridine as the template molecule and ethyleneglycoldimethacrylate as cross-linker. The polymer prepared was characterized for structural feature by FTIR and the thermal behavior by TGA. The kinetics of the reaction was found to follow by the so-called Ping-Pong-Bi-Bi mechanism. The kinetic parameters were determined by non-linear regression analysis and was obtained as Vmax = 0.692 mmol/min g, Km (alc) = 66.3 mM, Km (acid) = 1.52 mM and Ki = 60.0 mM.

Keywords: Molecularly imprinted polymer, esterification

Defects in ionic solid are very much common, which is increased with the increase in temperature. It causes the change in the value of many physical properties and varieties of physical parameters and the Madelung constant is one such parameter to control the structure of the crystals. Considering the loss of ions from lattice points as random, the examination of each of the defects individually is going to be unpredictable, thus leading to almost unattainment of the correct crystal structure with the theoretical calculations applying for available models. Here, in this present work, we have used some statistical methods and probabilistic approximation to introduce a novel idea of calculating the Madelung constant, analytically. To make the understanding more lucid, we have taken one of the very simple crystals, very popular for the crystallographic people, too, a 6:6 crystal (NaCl), for which a considerable number of Schottky defects are observed. During this study, we are bound to assume the random distribution of defects as Poisson distribution to calculate the Madelung Constant.

Unimolecular Dissociation of γ-Ketohydroperoxide via Direct Chemical Dynamics Simulations

Erum Gull Naz, Dr.Manikandan Paranjothy*
Department of Chemistry, Indian Institute of Technology Jodhpur, Rajasthan
naz.1@iitj.ac.in

Hydroperoxides (molecules containing -OOH group) are important in the gas and liquid phase oxidation of organic compounds. Organic hydroperoxides play a central role in the atmospheric ox- idation reactions and their degradation in troposphere results in low vapor pressure polyfunctional species that lead to the formation of secondary organic aerosols. The O-O bond in these compounds is weaker than C-C or C-H bonds and responsible for the formation of radicals. γ-ketohydroperoxide [3-(Hydroperoxy)propanal] is an important reagent in synthetic chemistry and in particular, oxidation reactions. It is considered to be a precursor for secondary organic aerosol formation in troposphere. Due to enhanced reactivity and limitations associated with analytical techniques, theoretical methods have been employed to study the unimolecular reactivity of hydroperoxides. A number of auto- mated reaction discovery techniques have been used to study the reactivity of γ-ketohydroperoxide and a large number of reactions have been reported in such studies. In the present work, we have investigated the unimolecular reaction dynamics of this molecule using electronic structure theory calculations and direct chemical dynamics simulations to assess the relevance of different reaction pathways. Classical trajectories were launched from the reactant well with fixed amounts of total energies and integrated on-the-fly using density functional B3LYP/6-31+G* model chemistry. Three dissociation channels among the previously reported reactions were identified as important. Korcek decomposition, which was proposed earlier as a source of carbonyl compounds from thermal decom- position of of γ-ketohydroperoxide, was not observed in the present high temperature simulations. However, trajectories showed formation of carbonyl compounds such as aldehydes via other path- ways. Results are compared with previous studies and detailed atomic level reaction mechanisms are presented. Further, Rice-Ramsperger-Kassel-Marcus (RRKM) rate constants were computed and compared with the trajectory data.

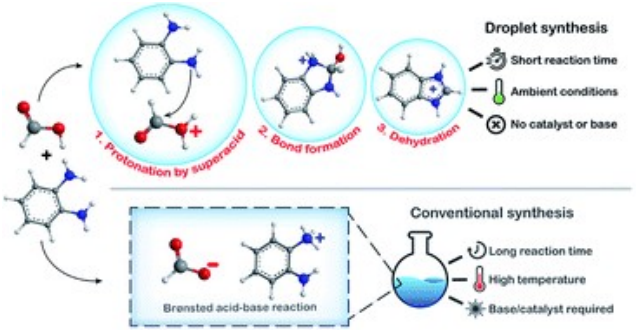
pallabchemistry@iitm.ac.in

We report a metal-free novel route for the accelerated synthesis of benzimidazole and its derivatives in theambient atmosphere. The synthetic procedure involves 1,2-aromatic diamines and alkyl or aryl carboxylicacids reacting in electrostatically charged microdroplets generated using a nano-electrospray (nESI) ionsource. The reactions are accelerated by orders of magnitude in comparison to the bulk. No other acid, base or catalyst is used. Online analysis of the micro droplet accelerated reaction products is performedby mass spectrometry. We provide evidence for an acid catalyzed reaction mechanism based on identification of the intermediate arylamides. Their dehydration to give benzimidazoles occurs in a subsequent thermally enhanced step. It is suggested that the extraordinary acidity at the droplet surface allows the carboxylic acid to function as a C-centered electrophile. Comparisons of thismethodology with



data from thin film and bulk synthesis lead to the proposal of three key steps in thereaction: (i) formation of an unusual reagent (protonated carboxylic acid) because of the extraordinary conditions at the droplet interface, (ii) accelerated bimolecular reaction because of limited solvation atthe interface and (iii) thermally assisted elimination of water. Eleven examples are shown as evidence ofthe scope of this chemistry. The accelerated synthesis has been scaled-up to establish the substituent dependence and to isolate products for NMR characterization.

The density (ρ), viscosity (η) and ultrasonic speed (U) of the pure solvents: 1,4-dioxane (DO), ethyl acetate (EA), tetrahydrofuran (THF) and solutions of the biologically active 1,10-bis(3-methyl-4-ethoxyacetylphenoxy)cyclohexane were investigated at four temperatures: 298, 303, 308 and 313 K over a wide range of concentrations (0.1–0.01 moldm-3) to understand molecular interactions in these solutions. Various acoustical and thermodynamic parameters such as specific acoustical impedance (Z), isentropic (adiabatic) compressibility (κs), Rao's molar sound function (Rm), van der Waals constant (b), internal pressure (π), free volume (Vf), intermolecular free path length (Lf), classical absorption coefficient {(α/f2)Cl}, viscous relaxation time (τ), Gibbs energy of activation (ΔG*), enthalpy of activation (ΔH*) and entropy of activation (ΔS*) were determined using the ρ, η and U data. A good to excellent correlation between a given parameter and concentration (C) is observed at all temperatures (T) and solvent systems studied.

The conventional epoxy resins are inefficient to satisfy the required properties in the field of advanced materials, which require high thermal and flame resistance. The properties of epoxy resins can be improved by modifying of epoxy backbone or using curing agents of different structures. Multifunctionalepoxy resins have attracted interest of researchers and producers.

2,4,6-Tris(4-hydroxyphenyl)-1,3,5-triazine was synthesized by cyclotrimerization of 4-cyanophenol using trifluromethanesulphonic acid as a catalyst at room temperature. Unsaturated polyester polyol of 2,4,6-tris (4-hydroxyphenyl)-1-3-5-triazine (ETPUP) was synthesized using alkali as a catalyst at 60 ◦C for 1 h and styrene was added as a reactive diluent (ETPUPSt). The structure of ETPUP was supported by FTIR and ^{1}H NMR spectroscopic techniques. Epoxy resin was cured by DSC at multiple heating rates under nitrogen atmosphere by using 20 % of 4,4'-diamino diphenylsulphone, 4,40-diaminodiphenylether, and 4,4'- diaminodiphenylcyclohexane as hardeners. Cured and uncured reins were also analyzed by TG analysis. Kinetic parameters were determined and discussed in light of nature of curing agents. Thermal decomposition behavior of the samples is also discussed in detail. Both the composites may be useful for load bearing housing units, and in electrical, electronic, and marine fields.

Molecular memory and dynamic cooperativity in monomeric enzymes

M. Panigrahy, S. Garani and A. Dua*
Department of Chemistry, Indian Institute of Technology Madras, Chennai- 600036, India
arti@iitm.ac.in

The classical Michaelis-Menten (MM) equation[1], represents a non-cooperative kinetic response of enzymes with either a single or non-interacting multiple binding site(s). The mean catalytic rate of several monomeric enzymes, however, shows deviations from this classical behavior. [2] This effect, termed as dynamic cooperativity, is believed to be associated with molecular mechanisms, stochastic reaction networks, that include enzymatic conformational fluctuations in product formation pathways. In spite of the latter, however, the present understanding of dynamic cooperativity is confined to mean kinetic measures, obtained from deterministic rate equations, which cannot account for fluctuations. Here, we consider a stochastic reaction network for a special class of monomeric enzyme, called mnemonical enzymes, which are known to exhibit both positive and negative (dynamic) cooperativity. We model their kinetics using the chemical master equation (CME) [3] to show how the emergence of dynamic cooperativity, at the molecular level, is inextricably linked to the multiplicity of monomeric enzyme numbers, enzymatic conformational fluctuations and molecular memory. Our results show that dynamic cooperativity is a transient phenomenon, which emerges due to temporal correlations between enzymatic turnovers, and vanishes as these correlations decay and molecular memory fades.[4]

Mechanical and electrical properties of Jute-Biomass-Styrenated MethacrylateEpoxy Resin sandwich composites

Dinesh Kundariya[1], Jignesh V. Patel[2], Parsotam H. Parsania*
[1]Tolani College of Arts and Science, Adipur (Kachchh), Gujarat, India
[2]*Department of Chemistry, Saurashtra University, Rajkot-360 005, Gujarat, India
[1]dineshkundariya@gmail.com

Sandwich composites of jute-biomass (banana, sugarcane, coir, wheat husk and groundnut)–styrenated methacrylateepoxy resin of 1,1'-bis(4-hydroxyphenyl) cyclohexane have been fabricated by compression molding technique at 110 °Cand 2 Bar pressure for 5 h. J-EBCMASt., J-B-EBCMASt, J-SC-EBCMASt, J-CO-EBCMASt, J-W-EBCMASt and J-GN-EBCMASt showed respectively tensile strength of 34.5,17.1, 11.4, 11.9, 20.7 and 13.1 MPa, and flexural strength of 32.3,21.6, 28.3, 11.2, 52.1 and 22.1 MPa, electric strength of 1.6, 1.2, 1.5, 1.3, 1.3 and 1.4 kV/mm and volume resistivity of 5.9 X 1012, 2.5 X 1012, 4.7 X 1011, 5.3 X 1012, 3.2 X 1012 and 2.3 X 1012 ohm cm. Considerably lower mechanical and electricalproperties of sandwich composites are due to different nature of biomass and random orientation. The composites may beuseful for low load bearing housing and electrical applications.

Kinetic and Mechanistic Studies in the Oxidative Regeneration of Carbonyl Compounds from Oximes by Quinolinium Dichromate

Anjali Purohit*, Pooja Tak and Priyanka Purohit
Chemical Kinetics Laboratory, Department of Chemistry, J.N.V. University, Jodhpur, India
pvkinetics@gmail.com

The oxidative deoximination of several aldo- and keto-oximes by quinolinium dichromate (QDC), in dimethylsulphoxide (DMSO), exhibited a first order dependence on QDC. A Michaelis-Menten type kinetics was observed with respect to oximes. The oxidation of ketoximes is slower than that of aldoximes. The rates of oxidation of aldoximes correlated well in terms of Pavelich-Taft dual substituent-parameter equation. The low positive value of polar reaction constant indicated a nucleophilic attack by a chromate-oxygen on the carbon. The reaction is subject to steric hindrance by the alkyl groups. The reaction of acetaldoxime has been studied in nineteen different organic solvents.

The solvent effect has been analysed by multiparametric equations. A mechanism involving the formation of a cyclic intermediate, in the rate-determining step is suggested.
